Text S1. Characterizations

The hydrodynamic size and zeta potential (ζ) of the MoS₂ nanosheets were determined using a Zetasizer instrument (NanoBrook Omini, Brookhaven, U.S.A.). For the size of MoS₂ testing, about 2 mL 30 mg/L of MoS₂ aqueous solution were added to plastic cell and according to the Stokes-Einstein formula to calculate the particle size. For the zeta potential (ζ) of the MoS₂ nanosheets testing, the palladium electrode was inserted into a quartz cell with 2 mL 30 mg/L of MoS₂ diluted with ultrapure water, based on the Smoluchowski formula to obtain the zeta potential value of MoS₂.

The morphologies of the MoS₂ nanosheets were characterized using transmission electron microscopy (TEM, Talos F200X, FEI, U.S.A.) and atomic force microscopy (AFM, MFP-3D Stand Alone, Asylum Research, U.S.A.). The exfoliated MoS₂ nanosheets were dispersed in ethanol and ultrasonicated for 10 min. Before TEM testing, the sample was firstly dropped onto the copper grid with carbon support and dried to keep the residual particles attached to the grid. Subsequently, the sample was measured by a microscope equipped with a Schottky emitter gun operated (at 200 kV). For AFM testing, the distributed MoS₂ nanosheets in ethanol were dropped onto a silicon wafer, then measured with an AC mode through Micro Cantilevers probe tip (240AC-NA, 70 kHz 2N/m) and AFM image was obtained by MFP-3D Stand Alone.

X-ray photoelectron spectroscopy (XPS, PHI 5000 Versaprobe III spectrometer, ULVAC-PHI, Japan) and Raman spectrometer (HORIBA LabRAM HR Evolution, Japan) were used to analyze the phase and chemical composition of the MoS₂ nanosheets. The samples were collected by filtration, and then dried in a vacuum freeze-

tryer. For XPS testing, the samples were firstly deposited on conductive adhesive, then using high-resolution scans with a PHI 5000 VersaProbe III equipped with a monochromatic Al anode (Al K α = 1486.7 eV) as an X-ray source to measured. For Raman testing, the samples were firstly deposited on glass slides, the spectra recorded by s LabRAM HR Evolution micro confocal Raman spectrometer with a 532 nm excitation laser. To real the complexation of Hg and NOM, solution-phase attenuated total reflectance Fourier Transform Infrared (ATR-FTIR) (Bruker Vertex 70v, Germany) spectroscopy measurements were conducted before and after Hg complexation with NOM through a diamond sample stage.

Text S2. Mercury uptake isotherms with different NOM concentration

Batch uptake isotherm tests were performed in the same Teflon vials, maintaining a fixed MoS₂ concentration of 4 mg/L, while varying initial Hg concentration from 0 to 45 mg/L and the NOM concentration at 0, 3, and 20 mg/L. After 24 hours of equilibration, the samples were filtered through 0.22 μ m PTFE filters, and the filtrates were analyzed with a direct mercury analyzer (DMA-80, Milestone, Italy). The isotherm data was fitted with the classical Langmuir model (**Eq. (1)**):

$$q_e = \frac{q_m K_L C_e}{1 + K_L C_e} \quad (1)$$

where q_e (mg/g) and C_e (mg/L) are the equilibrium Hg uptake capacity and the equilibrium Hg concentration, q_m (mg/g) is the maximum removal capacity, K_L (L/mg) is the Langmuir affinity constant.

Text S3. Separate Hg-NOM with the Amico Ultra-15 centrifugal filters

In order to quantify the Hg complexation by different fraction of NOM, an ultrafiltration membrane was used to separate Hg-NOM and free Hg. Firstly, a series of Amico Ultra-15 centrifugal filters with decreasing molecular weight cut-offs (MWCO) of 100 KDa, 30 KDa, 10 KDa, and 3 KDa were used to separate pristine NOM for obtained NOM MW fractionation (i.e., > 100 KDa, 30–100 KDa, 10–30 KDa, 3–10 KDa, <3 KDa). Subsequently, NOM with different molecular weights (> 100 KDa, 30–100 KDa, 10–30 KDa, 3–10 KDa) is mixed with Hg (10 mg/L of TOC, 0.5 mg/L of Hg), and then subjected to centrifugation in their respect MWCO membrane. The concentration of Hg in filtrate was determined by a direct mercury analyzer. In the control experiment, Hg solution without NOM was filtered by ultrafiltration membranes in the same condition.

Table S1. Pseudo-first-order and pseudo-second-order models for simulating Hg removal kinetics and the corresponding parameters.

NOM concentration (mg/L)	Kinetic models	Parameters	R^2	
0	Pseudo-first-order	K_1 (h ⁻¹) 0.37	q_e (mg/g) 3053.4	0.987
	Pseudo-second-order	K_2 (g/(mg•h)) 0.002	q_e (mg/g) 5000	0.999
20	Pseudo-first-order	K_1 (h ⁻¹) 0.7	q_e (mg/g) 1032.6	0.89
	Pseudo-second-order	K_2 (g/(mg•h)) 0.0005	q_e (mg/g) 2000	0.996

Table S2. Regression parameters of sorption isotherm data of Hg onto MoS₂ nanosheets by Langmuir models in the presence of NOM.

NOM concentration (mg/L)	Parameters	R^2	
0	q_m (mg/g) 5376.20	K_L (L/mg) 1.93	0.98
3	q_m (mg/g) 1963.40	K_L (L/mg) 20.93	0.87
20	q_m (mg/g) 1536.40	K_L (L/mg) 2.94	0.97
