**Text S1.** Chemicals and reagents.

All solutions were prepared with analytical or higher-grade chemicals and purified water (18.2 M $\Omega$  cm). Potassium ferrate was purchased from Sinopharm Chemical Reagent Co. Ltd (Shanghai, China). Fe(VI) solutions were prepared prior to each experiment by diluting the desired amount (1.1-1.2 g) of solid K<sub>2</sub>Fe<sup>VI</sup>O<sub>4</sub> to DI water (10-15 mL). Fe(VI) solutions were filtered with 0.45  $\mu$ m syringe filter membranes and used within 5 min. Caffeine (CAF) and paracetamol (PCT) stock solutions (10 mM) were prepared in ultra-pure water and ibuprofen (IBP) stock solutions (10 mM) were prepared in acetone. Ferric chloride (FeCl<sub>3</sub>), Sodium thiosulfate (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>), sulfuric acid (H<sub>2</sub>SO<sub>4</sub>), sodium sulfate (Na<sub>2</sub>SO<sub>4</sub>), Sodium phosphate dibasic (Na<sub>2</sub>HPO<sub>4</sub>) and sodium phosphate monobasic (NaH<sub>2</sub>PO<sub>4</sub>), 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic) (ABTS) were purchased from Sinopharm Chemical Reagent Co. Ltd (Shanghai, China). High performance liquid chromatography (HPLC) grade methanol (MeOH), acetonitrile (ACN) were purchased from Boer Chemical Reagent Co., Ltd (Shanghai, China). The standards for trihalomethanes (THMs), haloacetaldehydes (HALs), haloacetonitriles (HANs) and halonitromethanes (HNMs) with the highest purity available were purchased from Sigma-Aldrich (St Louis, Missouri, USA), CanSyn Chemical Corp. (Canada), and Aladdin Industrial Inc. (Shanghai, China). The detailed DBP information is available in Table S2.

**Text S2.** The measurement of fluorescence excitation-emission matrix (EEM).

EEM fluorescence spectra of the original sewage and treated samples were measured using a three-dimensional spectrofluorometer (F-7100 Fluorescence, HITACHI, Tokyo, Japan). Before the measurements, all of the samples were filtered with 0.45  $\mu\text{m}$  syringe filter membranes and diluted tenfold (UV absorbance  $<0.05 \text{ cm}^{-1}$  at 254 nm) to avoid inner-filtering effects (Yang and Hur, 2014). The fluorescence was scanned at a speed of 12000 nm/min in the wavelength range of (Ex, Em) = (200–450, 250–550 nm), with a slit width of 5 nm and a photomultiplier voltage of 400 V. Blank EEM spectra of ultrapure water was measured prior to sample analysis and used to subtract the water background. The obtained EEM data were then treated by eliminating first- and second-order Rayleigh and Raman scattering signals using an interpolation method and standardizing the unit of fluorescence intensity using the first-order Raman peak area of ultrapure water (Bahram et al., 2006; Lawaetz and Stedmon, 2009). The final fluorescent intensity was expressed in Raman Units (R.U.). Partition and fluorescence regional integration of five regions of EEM spectra were based on previous research and calculated using MATLAB R2019a (Chen et al., 2003).

**Text S3.** The measurement of size-exclusion chromatography-organic carbon detector (SEC-OCD).

The molecular weight distribution of DOM was measured by size-exclusion chromatography with an organic carbon detector (SEC-OCD). SEC was carried out using a polymethacrylate-packed column (250 mm × 20 mm, 3 μm), and installed on a Waters Alliance high performance liquid chromatography (HPLC, e2695, MA, USA) equipped with a Sievers M9 SEC organic carbon detector. Phosphate buffer (5.6 mM Na<sub>2</sub>HPO<sub>4</sub>/14.4 mM NaH<sub>2</sub>PO<sub>4</sub>) was used as the mobile phase and then was delivered with a HPLC pump at a flow rate of 1.0 mL/min to an autosampler (MLE, Dresden, Germany), and the injection volume was 250 μL. More information about SEC-OCD is available in a previous study (Zhang et al., 2021).

**Text S4.** UPLC conditions for emerging contaminants analysis.

PCT and IBP were detected with an HPLC (Agilent 1200) and equipped with an Waters C18 column ( $4.6 \times 150$  mm,  $5.0 \mu\text{m}$ ) with an injection volume of  $100 \mu\text{L}$ , and a flow rate of  $0.7 \text{ mL min}^{-1}$  was used. Detection wavelengths for PCT and IBP were set at 273 and 220 nm, respectively. To eliminate interference from peaks of impurities from sewage and other oxidation products after treatment, a gradient elution was used to separate the intended peak. Both the mobile phases were methanol (A) and ultrapure water (B) for PCT. The gradient elution procedure for PCT was designed as follows: 0 min 30:70 (A%/B%), 3 min 30:70 (A%/B%), 7 min 70:30 (A%/B%), 9 min 30:70 (A%/B%), 13 min 30:70 (A%/B%). The mobile phases were acetonitrile (A) and 10mM phosphoric acid (B) for IBP. The gradient elution procedure for IBP was designed as: 0 min 20:80 (A%/B%), 9 min 90:10 (A%/B%), 10 min 20:80 (A%/B%), 13 min 30:70 (A%/B%).

### **Text S5. Quantification Method of Fe(VI).**

The concentration of Fe(VI) stock solution was determined spectrophotometrically by measuring the absorbance at 510 nm using molar absorptivity ( $\epsilon_{\text{pH } 9} = 1150 \text{ M}^{-1} \text{ cm}^{-1}$ ). The concentration of residual Fe(VI) at defined time intervals was determined by the ABTS method. ABTS solutions (450  $\mu\text{M}$ ) were prepared in 0.2 M phosphate/0.6 M acetate buffers at pH 4.0 and 4.0 mL of ABTS solutions was used for rapid reaction with 2ml of the sample at defined time intervals, to measure the absorbance at 645 nm ( $\Delta A_{\text{w/o}}$ ) to calculate the concentration of residual Fe(VI) concentration. The concentration of Fe(VI) in sample was calculated by following equation:

$$[\text{Fe(VI)}] = [\text{ABTS}^{\bullet+}]_{\text{w/o}} \div 1.02 \times 3 = \Delta A_{\text{w/o}} \div \epsilon_{645} \div 1.02 \times 3$$

Where [Fe(VI)] represents the residual concentration of Fe(VI) in the samples collected at selected time intervals;  $[\text{ABTS}^{\bullet+}]_{\text{w/o}}$  represents the concentration of  $\text{ABTS}^{\bullet+}$  produced from the reaction of Fe(VI) with ABTS;  $\Delta A_{\text{w/o}}$  represents the change of the absorbance at 645 nm after completion of the reaction between Fe(VI) and ABTS.

**Table S1.** Major quality parameters for sewage.

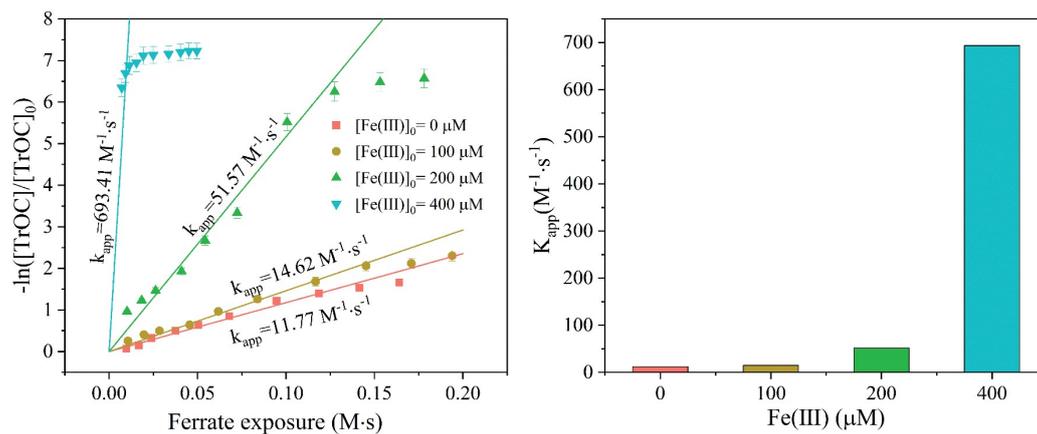

DOC (mg/L)	NH <sub>4</sub> <sup>+</sup> -N (mg/L)	UV <sub>254</sub>	Turbidity (NTU)	COD (mg/L)	TP (mg/L)
37	40	0.375	123	281	17.7

**Table S2.** Analytical methods and conditions for DBPs measurement.

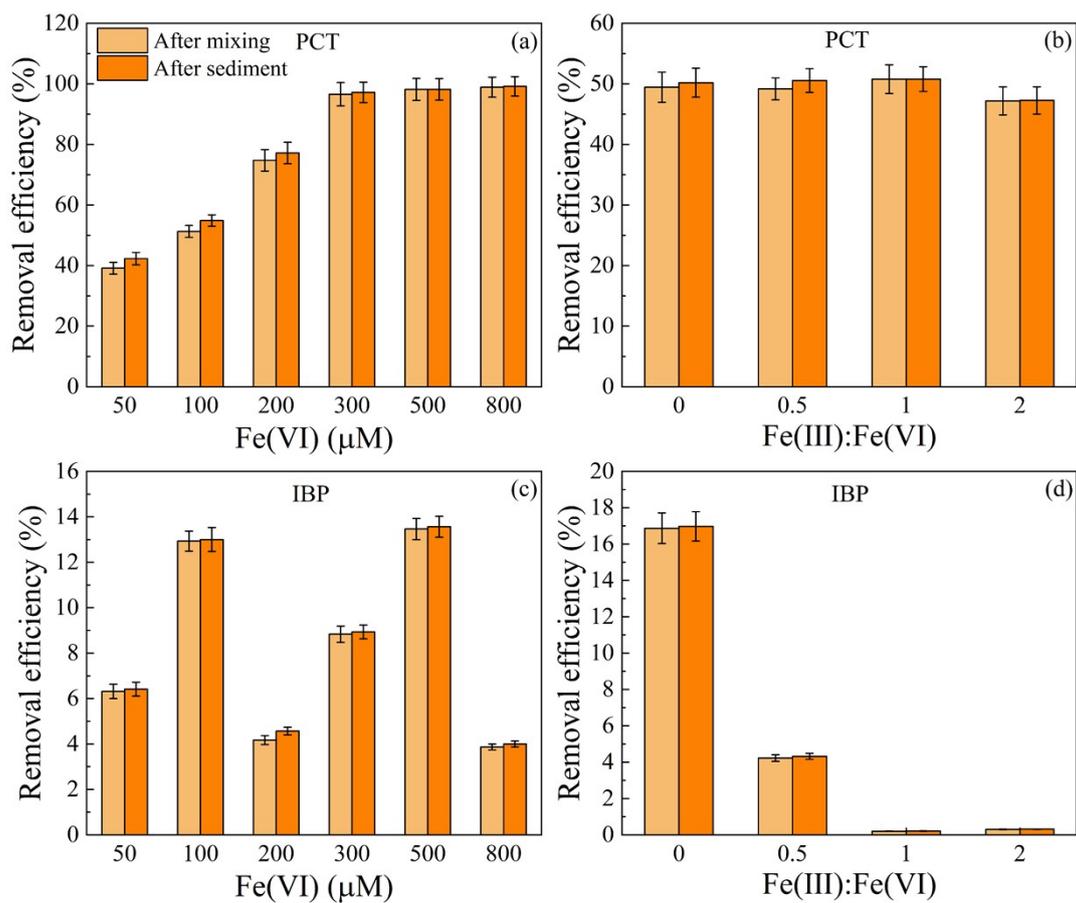

GC/ECD:	QP2010plus, Shimadzu Corporation, Japan		
Columns:	RTX-5, 30 m × 0.25 mm ID, 0.25 µm film thickness		
Carrier gas:	Nitrogen, constant flow at 3 ml per minute.		
Injection volume:	1 µL		
Temperature programmes:			
Vaporizing chamber:	200 °C		
	for THMs	for HANs and HNMs	for HAMs
GC column	Initial temperature at 30 °C for 10.5 minutes, then 14 °C per minute to 72 °C and hold for 1 minute and finally 40 °C per minute to 200 °C and hold for 2 minutes.	Initial temperature at 30 °C for 10 minutes, then 17 °C per minute to 72 °C and hold for 1 minute and finally 40 °C per minute to 200 °C and hold for 2 minutes.	Initial temperature at 50 °C for 8 minutes, then 20 °C per minute to 120 °C and hold for 2 minutes and finally 40 °C per minute to 220 °C and hold for 5 minutes.
Detector:	300 °C		

**Table S3.** Characteristics, sources and limit of quantitation of the DBPs.

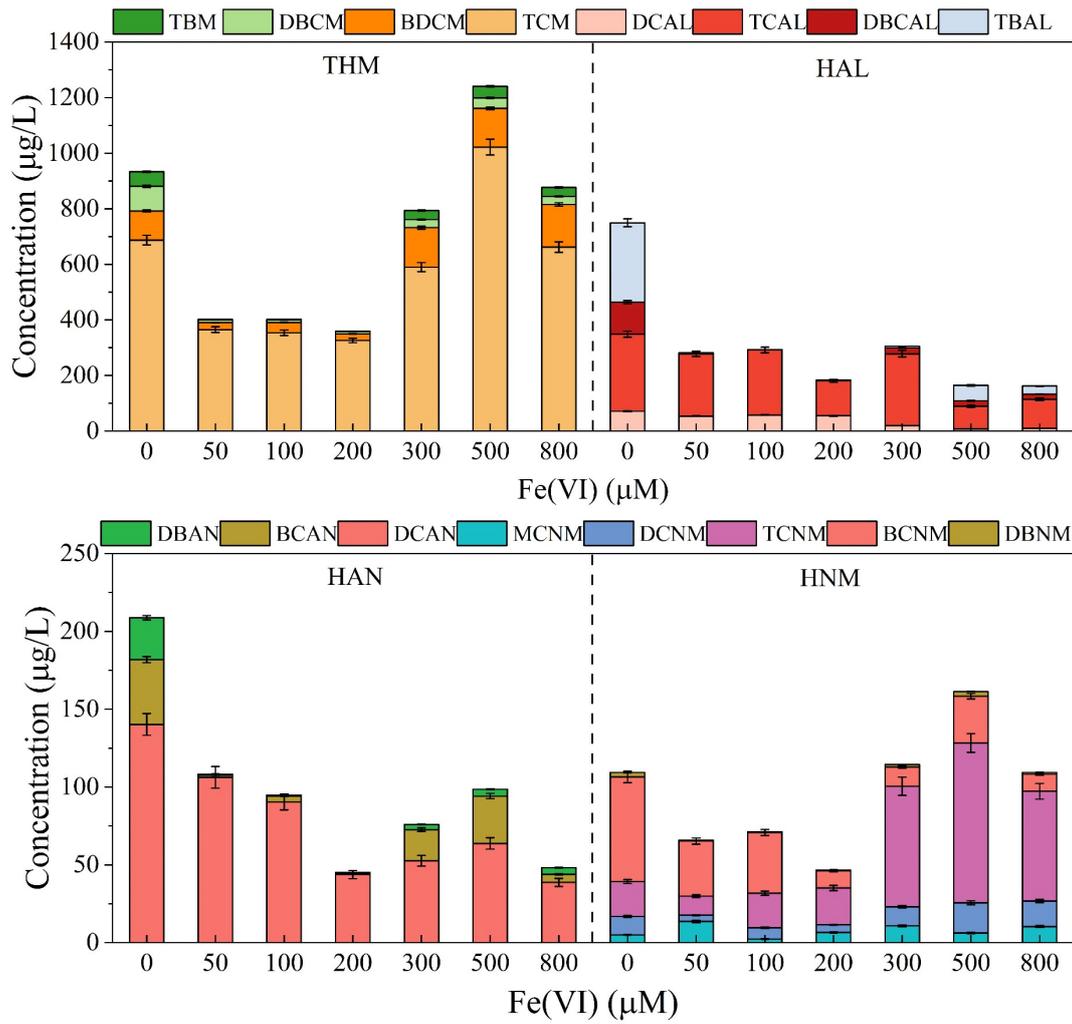

DBPs	CAS No.	Chemical formula	Molecular weight	LC <sub>50</sub> (M)	Source and purity
TCM	67-66-3	CHCl <sub>3</sub>	119.38	$9.62 \times 10^{-4}$	Supelco, 99%
