1. EXPERIMENTAL SECTION

1.1. Catalyst Synthesis.

1.1.1. Chemicals and materials

The $In(NO_3)_3 \cdot xH_2O$ ($\geq 99.9\%$) was purchased from Aladdin Chemical Reagent Co., Ltd. NaOH, ethylenediamine (EDA, $\geq 99.0\%$), tetraethyl orthosilicate (TEOS, the equivalent SiO_2 content is 28.4%), ethanol ($\geq 99.7\%$), ammonia (25~28 wt% in water) were purchased from Sinopharm Co., Ltd. All reagents used were analytical grade without any further purification. Additionally, throughout the entire experimental process, the deionized (DI) water used was self-prepared using an ultrapure water system of our laboratory. The synthesis methods of all samples are illustrated in Scheme S1.

1.1.2. Synthesis of regular In_2O_3 nanoparticles.

Two strategies involving hydrothermal synthesis and SiO_2 -templating were employed to fabricate traditional In_2O_3 nanoparticles with $InOH \bullet \bullet \bullet In$ FLPs. In the first method, 0.6 mmol of $In(NO_3)_3 \cdot xH_2O$ and 17 mL of DI water were added to a 25 mL stainless-steel autoclave, following the same treatment process as described above to obtain the $In(OH)_3$ -nanoparticle precursor. The precursor was then calcined for 5 h at 300 °C in air condition, resulting in a sample labeled as H-IO. As for the second method, SiO_2 microspheres were first synthesized by the Stöber method using TEOS in a mixed solution of ammonia and ethanol. Next, 1.2 g $In(NO_3)_3 \cdot xH_2O$ and 4.8 g SiO_2 microspheres were mixed in 30

ml of DI water with sonicating and magnetic stirring for 1 h to ensure homogeneity. The solution was then dried at 80 °C for about 12 h, and the resulting solid was directly calcined at 300 °C for 3 h. During this process the sample turned from white to pale yellow, indicating the formation of In₂O₃. The In₂O₃/SiO₂ mixture was ground, and dispersed in 2 M NaOH (50 times× excess by mass) to remove the SiO₂ by base etching at 80 °C while stirring for 24 h. Then the suspension was filtered and washed with DI water to ensure thorough removal of any trapped impurities before being dried at 60 °C for 12 h in a vacuum oven. The resulting sample was labeled as Si-IO after grinding.

1.1.3. *Synthesis of amine-modified In₂O₃ nanoparticles.*

The amine-modified In₂O₃ nanoparticles were synthesized by an impregnation method. 0.2 g of the prepared H-IO or Si-IO samples was added to 15 mL of EDA, and stirred at room temperature for 3 hours. Then the samples were centrifuged and washed for three times each with ethanol and deionized water. After that they were dried at 60 °C about 12 h in a vacuum oven. The obtained products were labeled as E-H-IO and E-Si-IO respectively. Additionally, to prevent the removal of EDA during the washing process, another portion of the impregnated H-IO samples were directly dried without undergoing the washing process, labeled as EI-H-IO.

1.2. Characterizations of In₂O₃ Catalysts.

Power X-ray diffraction (PXRD) patterns were recorded on a Miniflex600 diffractometer (Rigaku, Japan) with Cu K α radiation ($\lambda = 0.15418$ nm) in step mode between 10 ° to 70 °. SEM images were obtained on a JEOL JSM 6700F instrument (Japan) with an accelerating voltage of 5 kV. The obtained samples were also characterized by Sigma 500 VP (Carl Zeiss AG) field emission scanning electron microscope (FESEM) and EDS. Transmission electron microscope (TEM), high-resolution transmission electron microscope (HRTEM) images and selected area electron diffraction (SAED) pattern were examined on a JEM-2100 microscope (Japan) at 200 kV. The Brunauer-Emmet-Teller (BET) adsorption and desorption isotherm of N₂ and the adsorption and desorption isotherm of CO₂ were determined on a Kubo X1000 BET analyzer (China) at 77 K and 298 K, respectively, after a pretreatment of samples at 120 °C for 2 h. Fourier Transform Infrared (FT-IR) spectra were recorded on a NEXUS-470 spectrometer (Thermo Nicolet, USA). Ultraviolet–visible diffused reflectance spectra (UV–vis DRS) were tested on a Shimadzu UV-2600i spectrophotometer equipped with an integrating sphere attachment in the wavelength range of 220~800 nm. X-ray photoelectron spectra (XPS) measurements were performed on a ESCALAB 250Xi photoelectron spectroscopy (Thermo

Fisher Scientific, USA) at 1.0×10^{-9} mbar with monochromatic Al K α radiation. The XPS analyses were conducted at a test energy of 1486.6 eV, using a spot size of 500 μm . The XPS instrument was operated at a tube voltage of 15 kV and a tube current of 10 mA. Additionally, all the obtained binding energies were corrected with reference to C 1s peak at 284.8 eV. The solid-state nuclear magnetic resonance (NMR) experiment of high-resolution ^{13}C solid-state spectra was recorded using the ramp ^{13}C magic angle spinning (MAS) sequence at room temperature in a Bruker Avance III HD 400MHz spectrometer equipped with a double resonance solid probe (Bruker, Germany). Isotope tracing experiments were performed using $^{13}\text{CO}_2$, and the isotope product gases were measured on a Hiden HPR-20 EGA mass spectrometer (Hiden Analytical, UK). Thermogravimetry-mass spectrum analysis (TG-MS, Rigaku, Japan) was detected on a Thermo plus EV2/Thermo mass photo analyzer from 30 to 800 $^\circ\text{C}$ with a heating rate of 10 $^\circ\text{C}/\text{min}$ in an argon atmosphere. Room-temperature electron spin resonance (EPR) spectra were determined on an A300 ESR spectrometer (Bruker, Germany). CO_2 temperature programmed desorption (CO_2 -TPD) measurements were operated on AMI-300 chemisorption analyzer (Altamira Instruments, USA). Room temperature photoluminescence (PL) spectra were obtained a FS5 photoluminescence spectroscopy (Edinburgh Instruments, UK). Additionally, transient photocurrent response and Mott-Schottky analysis were conducted on a CHI660E electrochemical analyzer (CH Instrument, USA) with the former utilizing a 500W Xe lamp (CEL-PF300-T8, China). Electrochemical impedance spectrum measurements were conducted on an Autolab 302A electrochemical analyzer (Metrohm, Switzerland). 0.1 M sodium sulfate electrolyte was used in in the entire electrochemical and photoelectrochemical characterization procedures.

1.3. Catalytic Performance Tests.

Gas-phase photocatalytic rate measurements were performed using a flow reaction system. As depicted in Figure S6, a dedicated quartz tube was utilized to contain approximately 100 mg of the sample, which was positioned in the central flat region of the tube and sealed with quartz wool at bottom. The reaction system was supplied with a gas mixture consisting of 6 mL min^{-1} of H_2 and 2 mL min^{-1} of CO_2 ($\text{H}_2 : \text{CO}_2 = 3$), introduced into the gas path before connecting the quartz tube to the reaction setup and placing it in a heating furnace. The reactor temperature was controlled using an OMEGA temperature controller, with a thermocouple sensor in contact with the sample. Irradiation was carried out using an CEL-PF300-T8 Xe lamp at an optical density of 500 mW cm^{-2} . The product gases were analyzed using a GC-7920 gas chromatograph (GC) equipped with a flame ionization

detector (FID). The GC had two gas analysis channels: FID1 (ZKAT-PLOT Pora Q column) for hydrocarbon detection (CH_4 and CH_3OH), and FID2 (TDX-01 column) for CO and CO_2 detection. Both channels employed N_2 as the carrier gas.

1.4. *In-situ* DRIFTS of Adsorption Measurement

1.4.1. *In-situ* DRIFTS spectra of the adsorption of CO_2 .

In-situ DRIFTS experiments were performed on a Tensor II spectrometer (Bruker, Germany) equipped with a mercury-cadmium-telluride (MCT) detector. Prior to measurement, the catalysts were purged with argon at 250°C for 0.5 h. The background spectrum was obtained at 250°C in argon flow with a resolution of 4 cm^{-1} . Subsequently, the catalysts were exposed to a mixture of CO_2 and argon ($5\text{ mL min}^{-1}\text{ CO}_2$, and $55\text{ mL min}^{-1}\text{ Ar}$) under dark conditions for different times. The *in-situ* DRIFT spectra were recorded by collecting enough scans at a resolutions of 4 cm^{-1} until the spectrums were stabilized.

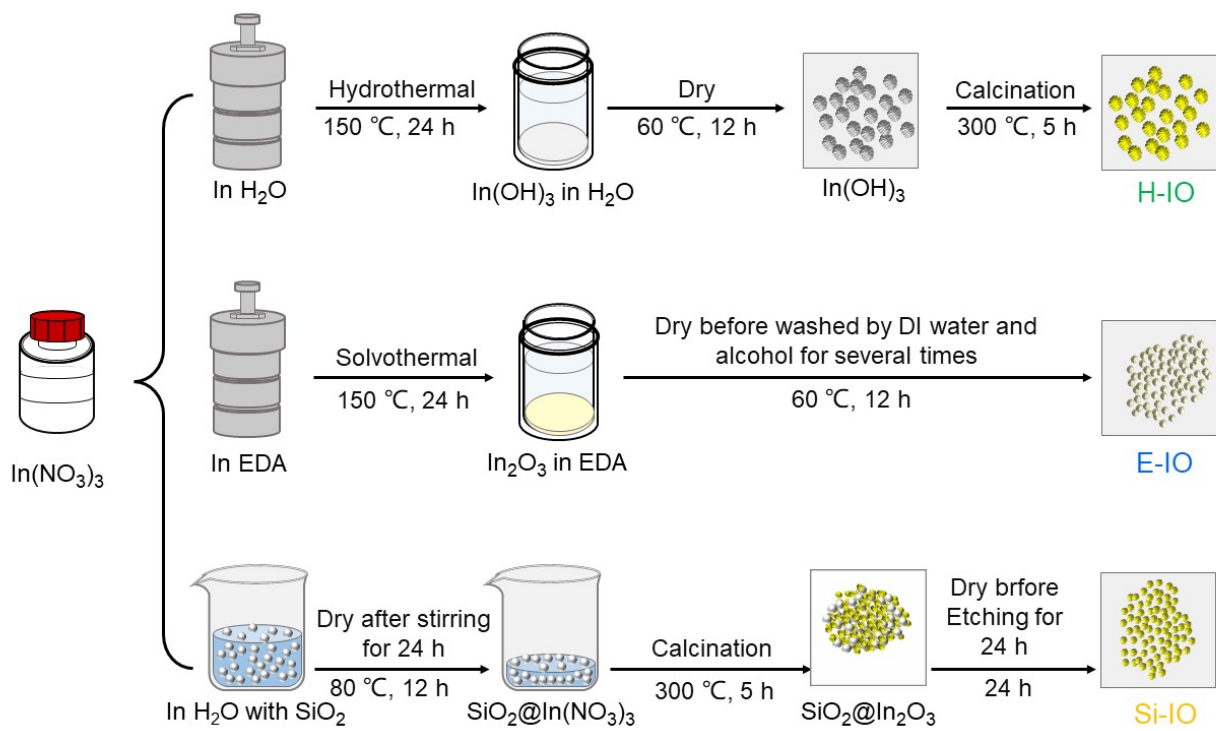

1.4.2. *In-situ* DRIFTS spectra of surface species under reaction conditions.

Prior to the formal signal acquisition during the reaction, a feed gas mixture of CO_2 , H_2 and Argon ($5\text{ mL min}^{-1}\text{ CO}_2$, $15\text{ mL min}^{-1}\text{ H}_2$ and $30\text{ mL min}^{-1}\text{ Ar}$) was introduced. After the infrared absorption spectrum of the sample reached stability, background spectrum was collected. Subsequently, illumination was introduced during the reaction to initiate the collection of infrared absorption spectrum. The *in-situ* DRIFT spectra were recorded by collecting enough scans at a resolutions of 4 cm^{-1} until the spectrums were stabilized.

1.5. Theoretical Calculations

The density functional theory (DFT) calculations were performed using the Cambridge Sequential Total Energy Package (CASTEP) computational codes. During the geometry optimization, lattice parameters and atomic positions were optimized simultaneously. Based on the experimental data, the grafting state model of EDA on surface of In_2O_3 was established by replacing one hydroxyl group on the surface of In_2O_3 with one amine group of EDA molecule. Additionally, one of the oxygen atoms coordinating with the amine group-coordinated indium atom was removed to establish $\text{InNH}_2\bullet\bullet\text{In}$ models. For calculating the electronic structures and density of states, the geometry optimization of (110) crystal face of In_2O_3 , $\text{In}_2\text{O}_{3-x}$, $\text{In}_2\text{O}_{3-x}(\text{OH})_y$, and $\text{In}_2\text{O}_{3-x}(\text{EDA})_y$ were calculated by the PBE method within Generalized Gradient-corrected Approximation (GGA) with the exchange-correlation potential. The Vanderbilt ultrasoft pseudopotential with a cutoff energy of 340 eV was used to ensure

the precision of the results. Brillouin zone integration was represented using the K-point sampling scheme of $2 \times 2 \times 2$ Monkhorst–Pack scheme. The convergence tolerance for geometry optimization was selected with the differences in total energy (1.0×10^{-5} eV/atom), the maximal ionic Hellmann–Feynman force (3.0×10^{-2} eV/Å), the stress tensor (5.0×10^{-2} GPa), and the maximal displacement (1.0×10^{-3} Å).
