Materials

Pyridine with purity ≥99.0, 3, 5 Lutidine with purity ≥98%, and Dimethyl phosphite with a purity of 98% were purchased from Sigma Aldrich. Triethylamine with purity ≥99.5, Ethylacetate, Acetonitrile and methanol with AR grade were purchased from Lobachemei. α-pinene oxide from TCI india.
Synthesis of ILs–

a) Triethylmethylammonium methyl phosphonate - A slightly modified procedure was followed to synthesize triethylmethylammonium methyl phosphonate TEMA[MeOPH₂] IL.¹ A 500 mL three-necked round-bottomed flask was equipped with a reflux condenser with a drying tube containing calcium chloride, a gas inlet adapter and an addition funnel with a pressure equalizer arm was flushed with nitrogen and filled with 250 mL acetonitrile. After that, 11.0 g of dimethyl phosphite (0.1 mol) and 10.0 g (0.0988 mol) of triethylamine were added dropwise under vigorous stirring and refluxed for 24 h under a nitrogen environment. After the completion of the reaction solvent was removed using a rotary evaporator at 70 °C by reducing the pressure and obtained product was washed with excess diethyl ether/ethyl acetate. Again traces of washing solvents were evaporated using a rotary evaporator and later put under a high vacuum to remove high boiling point impurities. In the end, the transparent liquid was obtained, which was transferred to air-tight bottles and stored in a desiccator under low pressure. The synthesis of ILs was shown in Scheme 1.

Scheme-S1. Synthetic procedure for ILs

b) 3,5 Lutidinium methyl phosphonate - Above mentioned procedure was followed to synthesize 3,5 lutidinium methyl phosphite Lut[MeOPH₂] in which 11.0 g of dimethyl phosphite (0.1 mol) and 10.58 g (0.0988 mol) of 3,5-Lutidine were added dropwise under vigorous stirring and refluxed for 24 h under a nitrogen environment. After completion of the reaction, the process described (TEMA[MeOPH₂] synthesis Section) above was used to purify the IL.
c) **Pyridinium methyl phosphonate** - Above mentioned procedure was followed to synthesize pyridinium methyl phosphite Py[MeOPHO$_2$] in which 11.0 g of dimethyl phosphite (0.1 mol) and 7.81 g (0.0988 mol) of pyridine was added dropwise under vigorous stirring and refluxed for 24 h under a nitrogen environment. After completion of the reaction, the process described (TEMA[MeOPHO$_2$] synthesis Section) above was used to purify the IL. The purity of all synthesized ILs was characterized using $^1$H, $^{13}$C and $^{31}$P NMR.

**Physicochemical characterizations**

All ILs were dried in a vacuum for 12 hours and handled carefully to minimize the moisture content. UV–vis absorption spectrums were recorded using a Varian Cary 500 UV-Vis NIR spectrophotometer. Phase transition points ($T_g$), crystallization temperatures ($T_c$), and melting points ($T_m$) were measured on a DSC NETZCH DSC 204 F$_1$ Phoenix thermal analyzer at the scan rate of 10 K min$^{-1}$. Decomposition temperatures ($T_d$) measurements were performed on a NETZSCH TG 209 F$_1$ Libra thermogravimeter under N$_2$ atmosphere at a heating rate of 10 K min$^{-1}$ in the temperature range of 303.15 to 1073.15 K. Densities ($\rho$) and sound velocities ($u$) measurements from 293.15 K to 343.15 K in 5 K steps were carried out using an Anton Paar Model DSA 5000 with a vibrating tube density meter with a resolution of 5 x 10$^{-6}$ g.cm$^{-3}$ and 0.01m.s$^{-1}$ for the density and speed of sound respectively. Dynamic viscosity ($\eta$) measurements from 293.15 K to 343.15 K in 5 K steps were carried out using an AMV$n$ Automated Micro Viscometer (Anton Paar, Graz, Austria) with a ball rolling capillary method.

3. Thermodynamic parameters investigation of synthesized ILs

(a) Conductivity ($\kappa$) and Walden rule

The classical Walden rule is usually used for assessing the ionicity of ILs. The ionic mobilities (represented by the equivalent conductivity $\Lambda = F \Sigma \mu_i Z_i$) and the fluidity $\varphi$ ($\varphi = \eta^{-1}$) of the medium can be related to the Walden rule by the movement of the ions. The relationship between the $\Lambda$ and $\eta$ of ILs can be described as:

$$\Lambda \eta = k \quad (S1)$$

Figure S11. Mechanistic studies by $^{31}$P NMR (a) TEMA[MeOPHO$_2$], (b) APO + TEMA[MeOPHO$_2$].
Where \( \Lambda \) is the molar electrical conductivity, \( \eta \) is the dynamic viscosity, and \( k \) is a temperature-dependent constant.

(b) Dynamic viscosity

The thermodynamic flow activation parameters Gibbs energy of activation (\( \dagger \Delta G \)), enthalpy of activation (\( \dagger \Delta H \)), the entropy of activation (\( \dagger \Delta S \)) and variation of the calorific capacity of activation (\( \dagger \Delta C_P \)) were estimated from the Eyring equation.\(^2\)

\[
\eta = \frac{hN_a}{V_M} \exp\left(\frac{\dagger \Delta G}{RT}\right) \quad (S2)
\]

where \( \eta \) is the dynamic viscosity, \( h \) is the Planck constant, \( N_a \) is the Avogadro constant, \( V_M \) is the molecular volume, \( R \) is the universal gas constant, and \( T \) is the absolute temperature.

According to the thermodynamic law \( \dagger \Delta G \),

\[
\dagger \Delta G = \dagger \Delta H - T \dagger \Delta S \quad (S3)
\]
The $V_m$, $\Delta H$, and $\Delta S$ are considered temperature-dependent herein. Thus, the constraints can be applied in broader ranges of temperature. $\ddagger \Delta G$ is calculated by isolating it from the Eyring equation. $\ddagger \Delta H$ is obtained by using the Gibbs-Helmholtz equation.

$$ \ddagger \Delta H = \left( \frac{\partial (\ddagger \Delta G/T)}{\partial (1/T)} \right) \quad \text{(S4)} $$

Thus, $\ddagger \Delta H$ is calculated by the derivation of function $\ddagger \Delta G/T$ with respect to $1/T$. $\ddagger \Delta C_p$ is given by the derivation of the activation enthalpy $\ddagger \Delta H$ to temperature. $\ddagger \Delta S$ is calculated from its thermodynamic equation (Equation S2). $\eta$ may be described by any previously mentioned empirical models for viscosity.

Figure S13. (a) Gibbs energy of activation, (b) enthalpy of activation, (c) standard molar entropy and (d) variation of calorific capacity of activation of synthesized ILs with temperature.
(c) Density

The investigation of the volumetric properties of ILs was done as per the literature. A straight line can be obtained according to plot \( \ln \rho \) against \( T/K \). The \( \ln \rho \) against \( T/K \) can be fitted by the following empirical equation:

\[
\ln \rho = b - \frac{\alpha}{T} \quad \text{(S5)}
\]

Where \( b \) is an empirical constant and \( \alpha \) is the thermal expansion coefficient.

![Figure S14](image)

Figure S14. (a) Molecular volume, (b) standard molar entropy, (c) thermal expansion coefficient and (d) lattice energy.

At 298.15 K, the molecular volume, \( V_m \), standard molar entropy, \( S^0 \), and lattice energy, \( U_{\text{POT}} \), of the ILs can be obtained from the experimental density by the following equations:

\[
V_m = \frac{M}{\rho N_a} \quad \text{(S6)}
\]
\[ S^0 = 1246.5 \cdot (V_m) + 29.5 \quad (S7) \]

\[ U_{POT} = 1981.2 \cdot \left( \frac{\rho}{M} \right)^{1/3} + 103.8 \quad (S8) \]

where, \( M \) is molar mass, \( \rho \) is the density, and \( N_a \) is Avogadro’s constant.

4. Polarizability/ dipolarity of synthesized ILs

Kamlet taft parameters

The negative solvatochromism of Reichardt's dye has been widely used to investigate the polarity of ILs. Reichardt's dye has a significant permanent dipole moment for dipole-dipole or dipole-induced dipole interactions, an effective polarizable arrangement for dispersion interactions with a high electron-pair donor for hydrogen bonding interactions. The significant negative solvatochromism of dye is due to different dipolar excited states of the molecule. When IL polarity increases, the molecule's ground state is stabilized in solvation relative to the excited state. IL polarity parameters, \( E_{NT}^N \), is determined by intermolecular charge-transfer absorption of the dye in an IL. The normalized \( E_{NT}^N \) represents a solvent polarity normalized using water and tetramethyl silane. 4-nitroaniline and N, N-diethyl-4-nitroaniline are commonly used to evaluate these parameters by solvatochromic comparisons of UV-spectra. This indicates the hydrogen-bond-donor acidity (\( \alpha \)), hydrogen-bond-acceptor basicity (\( \beta \)), and polarizability of ILs.

(1) Solvent Polarizibility (\( \pi^* \))

\[ \pi^* = \frac{\nu(DENA)_{\text{max}} - 27.52}{-3.183} \quad (S9) \]

where, \[ \nu(DENA)_{\text{max}} = \frac{10000}{\lambda_{\text{max}}(DENA)} \]

(2) Hydrogen Bond Donator Capacity (\( \alpha \))
\[ \alpha = \frac{E_r(30) - 14.6(\pi^* - 0.23) - 30.31}{16.5} \]  
(S10)

where,
\[ E_r(30) = \frac{28591}{\lambda_{\text{max}}(RD)} \]

(3) Hydrogen Bond Accepter Capacity (\(\beta\))

\[ \beta = \frac{1.035 \times \nu_{\text{max}}(DENA) - \nu_{\text{max}}(4NA) + 2.64}{2.8} \]  
(S11)

where, \( \nu_{\text{max}}(4NA) = \frac{10000}{\lambda_{\text{max}}(4NA)} \)

(4)
\[ E_N^r = \frac{E_r(30) - 30.7}{32.7} \]  
(S12)

RD = Reichardt's dye

DENA = N,N-diethyl-4-nitroaniline

NA = 4-Nitroaniline

Reaction conditions: 0.5 mL APO, 413.15 K, 1.5 mL ILs, 3 h.
Figure S15. Show GC standard data of TCV and obtained reaction mixture.

5. Recyclability of TEMA[MeOPHO₂] IL – When the reaction was finished, a biphasic system was created by mixing water and ethyl acetate in a separating funnel. TEMA[MeOPHO₂] was isolated in the aqueous phase, while the products TCV and CA were isolated in the ethyl acetate phase. To eliminate minute organic contaminants, the recovered aqueous phase underwent one more ethyl acetate wash. To get regenerated TEMA[MeOPHO₂] IL, rotary evaporation of the aqueous phase is performed. ¹H NMR was used to assess the purity of recycled IL.
