97

98

Section S3. Single-crystal X-ray diffraction:

99 **Single-crystal X-ray diffraction:** Single-crystal X-ray diffraction data were acquired by a
100 Bruker D8 Venture Metaljet PHOTON II diffractometer equipped with GaKa radiation
101 ($\lambda = 1.34139 \text{ \AA}$). The suitable crystal was selected and kept at 193 K during data
102 collection. The structural determination was performed using Olex2, employing the
103 Direct Methods with the SHELXS, followed by refinement using the SHELXL
104 refinement package and Least Squares minimization. Anisotropic refinement was
105 applied to all nonhydrogen atoms, while hydrogen atoms bonded with carbon atoms
106 were included at calculated positions and refined using a riding model.

107

Section S4. Density functional theory (DFT) calculations

108 The first-principles density functional theory (DFT) calculations for the determination
109 of static adsorption energies were carried out using the CP2K code. The adsorption
110 energy can provide valuable insights into the interactions between the SO₂/CO₂/N₂ and
111 the MFSIX-Cu-TPA. All the simulations employed a combination of Gaussian and
112 plane-wave basis sets. The core electrons were represented with norm-conserving
113 Goedecker-Teter-Hutter pseudopotentials. Additionally, the valence electron wave
114 function was expanded in a double-zeta basis set with polarization functions. This is
115 added by an auxiliary plane wave basis set. A kinetic cut-off energy of 360 eV was
116 utilized to ensure accurate calculations. The exchange-correlation function employed
117 in these calculations was the Perdew-Burke-Enzerhof (PBE) generalized gradient
118 approximation. Each configuration was optimized with the Broyden-Fletcher-
119 Goldfarb-Shanno (BFGS) algorithm, with self-consistent field (SCF) convergence
120 criteria of 1.0×10^{-6} au. Grimme's DFT-D3 model was also utilized to account for van
121 der Waals interactions, providing a more accurate description of the whole system.

122

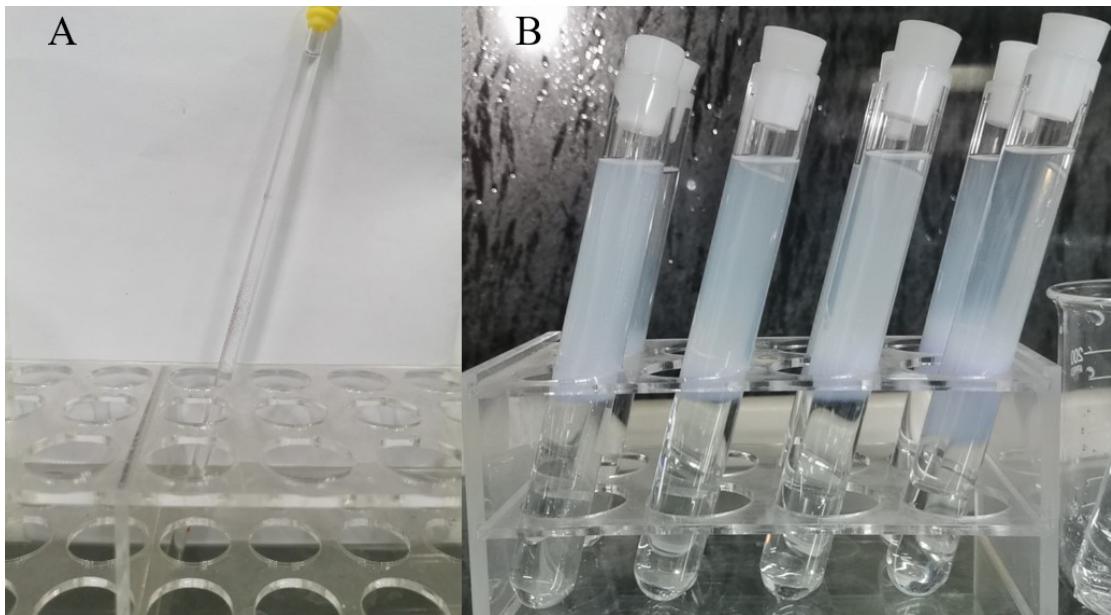

123 **Section S5. Grand Canonical Monte Carlo (GCMC) simulations**

124 Grand Canonical Monte Carlo (GCMC) simulations of single-component adsorption
125 isotherms were all performed using RASPA package.¹ The structure of SNFSIX-Cu-
126 TPA was firstly optimized via DFT geometry optimization in the Section S5. All Monte
127 Carlo simulations were performed using the Lennard-Jones (L-J) potential in a rigid
128 framework. The Lennard-Jones parameters for adsorbate-host interactions were
129 obtained using the Lorentz-Berthelot mixing rules. The force field parameters for CO₂
130 and N₂ were taken from the TraPPE force field, where both molecules were considered
131 rigid.² Additionally, the force field parameters for SO₂ were taken from Ketko's
132 optimized SO₂ model, which includes a harmonic O–S–O bending angle potential with
133 the S–O bond length fixed.³ Van der Waals interactions were calculated using a 12 Å
134 cutoff, and the minimum image convention was satisfied using a 2x2x2 supercell.
135 Besides, the Ewald summation method was used to compute Coulomb interactions. For
136 all GCMC simulations, sampling began after 1x10⁴ initialization cycles and
137 thermodynamic properties were sampled over the next 10⁵ cycles.
