Materials and Methods

All commercially available reagents were of reagent grade and used without further purification. Dichloromethane (CH$_2$Cl$_2$), n-hexane, acetonitrile, tetrahydrofuran (THF), and toluene were freshly distilled before each use. $^1$H NMR spectra were recorded at 25 °C using a Bruker Advance DPX 250 or DPX 400 spectrometer. $^{13}$C NMR spectra were recorded at 25 °C using a Bruker DPX 400 spectrometer. Matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF-MS) was performed using a Bruker Daltonics LRF20 with dithranol (1,8,9-trihydroxyanthracene) as the matrix. Recycling size exclusion chromatography (SEC) was performed using a JAI model LC9201 equipped with JAIGEL-1H, JAIGEL-2H, and JAIGEL-3H columns using THF (DUKSAN Pure Chemicals) as the eluent. UV–is absorption spectra were measured using a JASCO V-660 spectrometer with a thermostatic cell holder coupled with a controller (ETCS-761, JASCO), and fluorescence spectra were recorded using a JASCO FP-6300 spectrofluorimeter with a temperature controller (ETC-273T, JASCO). All spectral measurements were performed using a quartz cuvette with a path length of 1 cm. Infrared absorption spectra were recorded using a Fourier-transform infrared (FT-IR) (JASCO FT/IR-4700) spectrometer. A transmission electron microscope (TEM) was operated at 120 kV (TEM, JEM-1400, JEOL, Tokyo, Japan) to capture images. For TEM measurements, a drop of each sample in methylcyclohexane was placed on a carbon-coated copper grid and allowed to evaporate under ambient conditions. The sample was stained by placing a drop of uranyl acetate solution (2 wt%) onto the surface of the sample-loaded grid. The deposited sample was allowed to rest for 1 min at minimum, after which the excess solution was wicked off using filter paper. The images were acquired with Veleta and Tengra CCD cameras (EMSIS, Germany) with 1 and 5.3 MP resolutions, respectively. A scanning electron microscope (SEM, 7610F-Plus, JEOL Ltd.) was used at room temperature, and the samples were prepared by coating on the silicon wafer. Atomic force microscopy (AFM, NX10, Park Systems) images were obtained. Each sample used for AFM measurements was dropped and spin-coated onto a freshly cleaved mica surface.

Non-linear regression for estimating the thermodynamic parameters

The degree of aggregation ($\alpha_{agg}$) for PD$_{Zn}$ and PD$_{Cu}$ obtained from apparent absorbance changes at the absorption maxima was plotted as a function of absolute temperature ($T$). The elongation enthalpy ($\Delta H_e$) and equilibrium constant of the nucleation step ($K_n$) for PD$_{Zn}$ were estimated by the nonlinear least-squares fitting method using eqs (S1) and (S2) from elongation
and nucleation regimes, respectively, where $T_e$ is the critical elongation temperature at a given concentration, $R$ is the ideal gas constant, and $\alpha_{SAT}$ is introduced as a parameter to ensure that $\frac{\alpha_{agg}}{\alpha_{SAT}}$ does not exceed unity.

\[
\alpha_{agg} = \alpha_{SAT} \left[ 1 - \exp \left( \frac{-\Delta H_e}{RT_e^2} (T - T_e) \right) \right]
\]  
(S1)

\[
\alpha_{agg} = \alpha_{SAT} \left[ \frac{1}{3K_a^3} \exp \left( \frac{2}{1 - \frac{\Delta H_e}{RT_e^2}} (T - T_e) \right) \right]
\]  
(S2)

**Estimation of twist angles between adjacent porphyrin units**

The transition dipole moment $\mu$ was estimated from Soret absorption bands of PD$_{Zn}$ in MCH at 373 K using eq. S3, where $f$ is oscillator strength, $\tilde{\tau}$ is full width at half-maximum of the Soret band, $\varepsilon_{max}$ extinction coefficient at absorption maximum, $e$ is the charge of an electron, $\tilde{\nu}$ is the mean absorption frequency of the Soret band in wavenumber, $m_e$ is the mass of an electron, and $\hbar$ is Plank’s constant.

\[
f = 4.32 \times 10^9 \varepsilon_{max} \Delta \omega_1 = \left( \frac{8\pi^2 m_e \tilde{\nu}}{(3\hbar^2)} \right) |\mu|^2
\]  
(S3)

The twist angle between adjacent porphyrin units ($\theta$) was estimated using eq. S4, where $\Delta E$ is the apparent splitting energy observed from absorption spectra of PD$_{Zn}$ in MCH at 293 K, $\mathbf{\tilde{\mu}}_1$ and $\mathbf{\tilde{\mu}}_2$ are vectors of transition dipole moments, $r$ is the center-to-center distance of porphyrin units, $\mathbf{\tilde{r}}_{12}$ is the corresponding unit vector, $\phi$ is the rotation angle of monomer units in helical turns, and $\varepsilon_0$ is vacuum permittivity.

\[
\Delta E = \left[ \frac{\mathbf{\tilde{\mu}}_1 \cdot \mathbf{\tilde{\mu}}_2 - 3(\mathbf{\tilde{\mu}}_1 \cdot \mathbf{\tilde{r}}_{12})(\mathbf{\tilde{\mu}}_2 \cdot \mathbf{\tilde{r}}_{12})}{4\pi \varepsilon_0 r^3} \right] = \frac{\mu^2}{4\pi \varepsilon_0 r^3} \left[ \cos \phi - 3 \cos \theta \cos (\theta - \phi) \right]
\]
