Figure S14. Conformation analysis of the mono HFIP-carbonate

The DFT calculation of the two representative conformations I-a and I-a' of the model HFIPterminated carbonate was performed to investigate the origin of the unique reactivity of the HFIPterminated carbonate. The calculation results indicated that conformation I-a was highly stable compared to I-a' ( $\Delta G = +29.2$  kcal/mol). This energy difference was caused by the intramolecular hydrogen bond between the carbonyl oxygen (O<sub>2</sub>) and the hydrogen of the HFIP moiety (H1) in I-a (H1-O<sub>2</sub>: 2.21 Å). The highly electron-deficient proton atom H1 by the trifluoromethyl groups is a good hydrogen bond acceptor. This attractive interaction reflects the bond angle of C1–O1– C2. The I-a angle is smaller than that of I-a' (I-a: 116.7°, I-a': 120.7°). Another conformation I-a', in which the hydrogen atom H1 is distal from the carbonyl oxygen atom O<sub>2</sub>, is disfavored because of the electronic repulsion between the fluorine atoms (F1 and F2) and oxygen O<sub>2</sub>.
