General procedures

Materials

All synthesis reactions were performed in a nitrogen-filled glovebox. Starting materials and reagents were purchased from commercial sources and used without further purification unless otherwise specified. Dried and degassed solvents were obtained via a Grubbs Solvent Purification System. The starting materials $[\text{Pt}(\text{COD})\text{I}_2]$ (COD = 1,5-cyclooctadiene) and $[\text{Pt}(\text{CNxyl})_2\text{I}_2]$ (**3^{xyl}**, xyl = 2,6-dimethylphenyl) were prepared following reported literature.^{1,2} The synthetic procedure of $[\text{Pt}(\text{CNPhOMe})_2\text{I}_2]$ (**3^{PhOMe}**, PhOMe = 4-methoxyphenyl) is described below. Tetrabutylammonium hexafluorophosphate, used as a supporting electrolyte for cyclic voltammetry experiments, was recrystallized from hot ethanol, and ferrocene, used as an internal standard for cyclic voltammetry experiments, was sublimed prior to use.

Physical Methods

^1H , $^{13}\text{C}\{^1\text{H}\}$, and ^{19}F NMR spectra were recorded at room temperature using a JEOL ECA-400, JEOL ECA-500, or ECA-600 NMR spectrometer. Infrared (IR) spectra were obtained using a Thermo Nicolet Avatar FT-IR spectrometer with a diamond ATR. The ESI-MS experiments were carried out at Texas A&M University, Department of Chemistry, Mass Spectrometry Facility. Cyclic voltammograms were recorded using a CH Instruments 602E potentiostat interfaced with a nitrogen-filled glovebox. Samples were dissolved in MeCN with 0.1 M tetrabutylammonium hexafluorophosphate as the supporting electrolyte, and recorded using a glassy carbon working electrode, platinum wire counter electrode, and silver wire pseudoreference electrode. Ferrocene was added at the end of each measurement as an internal standard, and all potentials are referenced to the ferrocenium/ferrocene redox couple. UV-vis absorption spectra were recorded in dichloromethane in screw-capped 1 cm quartz cuvettes using an Agilent Cary 8454 UV-vis spectrophotometer. Steady-state emission and excitation spectra were recorded using a Horiba FluoroMax-4 spectrofluorometer. Air-free samples for emission spectra were prepared in a nitrogen-filled glovebox using dry, deoxygenated solvents. Room-temperature emission measurements in solution were housed in 1 cm quartz cuvettes with septum-sealed screw caps, and samples for low-temperature emission were contained in a custom quartz EPR tube with a high-vacuum valve and cooled in liquid nitrogen using a finger Dewar. The quantum yields of complexes doped into poly(methyl methacrylate) (PMMA) thin films were recorded using a Spectralon-coated integrating sphere (150 mm diameter, Labsphere) exciting at 365 nm. Phosphorescence lifetimes were measured on a Horiba DeltaFlex Lifetime System, using 330 nm excitation. The thermogravimetric analyses (TGA) were conducted with a TGA 5500 using a 100 μL platinum pan with a heating rate of 10°C/min under nitrogen atmosphere.

PMMA Film Fabrication

A solution of PMMA (98 mg, 35 kDa) in dichloromethane (1.0 mL) was prepared at room temperature inside a nitrogen-filled glovebox. Then, the respective platinum complex (2 mg, 2 wt.%) was added to the solution and stirred until the solution became clear. The solution was then drop-coated onto a quartz substrate and dried at room temperature overnight prior to use. *X-ray Crystallography Details*

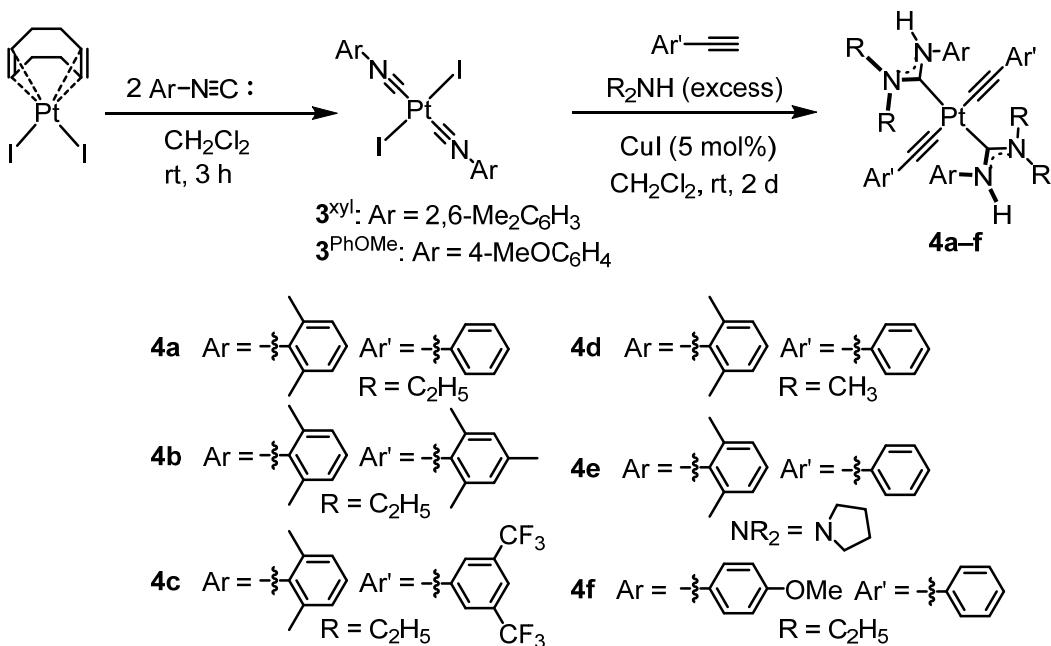

Crystals were mounted on a Bruker Apex II three-circle diffractometer using MoK α radiation ($\lambda = 0.71073 \text{ \AA}$). The data was collected at 123(2) K and was processed and refined within the APEXII software. Structures were solved by intrinsic phasing in SHELXT and refined by standard difference Fourier techniques in the program SHELXL.³ Hydrogen atoms bonded to carbon were placed in calculated positions using the standard riding model and refined isotropically; all non-hydrogen atoms were refined anisotropically. N–H hydrogen atoms were located in the difference map and refined isotropically, restraining the N–H bond distance to 0.88 Å and constraining the isotropic displacement parameter to be 1.2× that of the N atom it is bonded to. The crystal of **4a** was found to be a non-merohedral twin with two unit cell domains. For this structure the data was integrated against both unit cell domains, and the absorption correction was performed in TWINABS. Final refinement was done against both unit cell domains.

DFT Calculations

Geometries for the S₀ and T₁ states of **1b**, **2b**, and **4a**, were computed using the (U)B3LYP-D3 functional with a 6-311G(d,p) basis set for C, N, and H and an SDD basis set with effective core potential (ECP) for Pt. Vibrational frequency calculations verified the nature of the stationary points. All reported structures are minima on the potential energy surface. Reported single-point energies were computed at the M06-2X level using the same basis sets. HOMO-LUMO energy gaps were computed by TD-DFT calculations using the optimized S₀ state geometries of **1a**, **2a**, and **4a** at the M06-2X level. All calculations were performed employing Gaussian16, C.01, and spin density and molecular orbital plots were prepared using Gauss View 6.0.16.

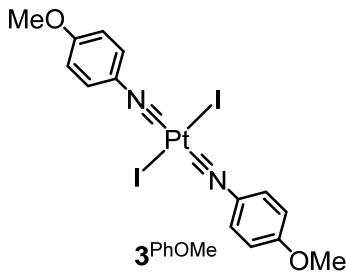

Dissociative ³MC state structures were located by selectively elongating the Pt–C bond of the ligands followed by optimization in the triplet state. Relative energies of the lowest energy ³MC structures of **1a** (dissociative isocyanide ligand), **2a** (dissociative ADC ligand), and **4a** (dissociative ADC ligand) compared to their corresponding T₁ states were determined. Spin density plots (Fig. S35–S37) revealed large coefficients around the metal center for all three ³MC state structures.

diiodobis(4-methoxyphenyl isocyanide)platinum(II) (**3^{PhOMe}**)

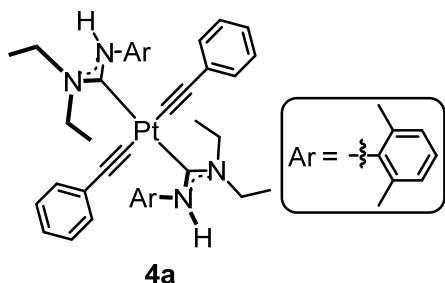

[$\text{Pt}(\text{COD})\text{I}_2$] (300 mg, 0.542 mmol) and 4-methoxyphenyl isocyanide (144 mg, 1.08 mmol) were combined in 10 mL of CH_2Cl_2 , and the mixture was stirred at room temperature inside the glovebox for 24 h. The solvent was evaporated using rotary evaporation. The product was purified by recrystallization from $\text{CH}_2\text{Cl}_2/\text{pentane}$ to form a brown powder. Yield: 79% (310 mg, 0.433 mmol).

¹H NMR in CDCl_3 (400 MHz). δ 7.46 (d, $J = 8.8$ Hz, 4H, ArH), 6.93 (d, $J = 8.8$ Hz, 4H, ArH), 3.85 (s, 6H, OCH₃) ppm. **¹³C{¹H} NMR** in CDCl_3 (101 MHz) δ 161.4, 128.5, 118.4 (Pt-CN-Ar), 115.1, 115.0, 55.9 (OCH₃) ppm. **FT-IR** (cm^{-1}) 2200 ($\tilde{\nu}_{\text{CN}}$).

General Procedure for the Synthesis of bis-ADC Complexes 4a–4f

The respective diiodobis(isocyanide)platinum(II) complex (**3^{xyl}** or **3^{PhOMe}**) was dissolved in CH₂Cl₂ (2 mL), followed by addition of the secondary amine (6 mL), 2.2 equivalents of arylacetylene and 5 mol% of CuI (1.3 mg, 0.0075 mmol). The resulting mixture was stirred at room temperature for 2 days. The mixture was diluted with 50 mL of CH₂Cl₂ and washed with deionized water four times, and the organic layer was collected and dried over MgSO₄ and filtered. The filtrate was evaporated under vacuum to obtain an oily crude product. Diethyl ether was subsequently added to the oily material and stirred for 30 minutes to extract the desired compound. After removing the solvent, the obtained product was further purified by recrystallization from CH₂Cl₂/pentane. The pure product was obtained after drying under vacuum.

Table S14. Electronic energies in a.u for the species in this study. Molecules were optimized at the (U)B3LYP-D3 functional with a 6-311G(d,p) basis set for C, N, and H and an SDD basis set with effective core potential (ECP) for Pt. Electronic energies were computed at the M062-X level with the same basis sets.
