1. Simple computational protocol for modelling the Raman spectrum of organic solids as dimers

$$\frac{N_c}{4} + 1$$

- 1- To model an organic molecule containing N_c carbons, we start by creating approximately $\frac{N_c}{4} + 1$ conformers (depending on rigidity) of a single molecule (monomer) in Avogadro and export each set of cartesian atomic coordinates to a .xyz file.
- 2- Then, each monomer geometry is pre-optimized with ORCA at the r²SCAN-3c level of theory in gas phase. An example input file can be used from section 3.1. The optimized monomers are ranked by their final single point energies (SPE), and the two most stable conformers are selected.
- 3- For each of the two pre-optimized monomers, we create, again with Avogadro, at least 8 dimer geometries with various relative positioning by means of rigid transformations. When applicable, we prioritize the hydrogen bonds between molecules followed by π -stacking placements.
- 4- The dimers are optimized with ORCA at the r²SCAN-3c level of theory in gas phase, with the TightOpt command.
- 5- The optimized dimers are again ranked by SPE, and the single most favorable geometry is used to calculate the Raman spectrum at the same level of theory still, with an input file using the commands shown in the example in section 3.2. If an imaginary frequency is found (in an ORCA output file, typically above all the vibration information, near the SPE), a new conformer must be generated. When a spectrum without imaginary frequencies is obtained, the spectral information can be obtained from the output file.
- 6- To extract the spectral data, the tool orca_mapspc is used with the following command:

```
orca_mapspc [OUTPUT FILE NAME] raman -cm -w04 -x00 -x14000 -n4000
```

And the generated .stk file is used for processing with the correlation software.

Figure S1. Match scores for the twelve initial compounds, calculated as single molecules (“monomers”), with r²SCAN-3c in gas phase. When only one molecule is modelled, several false positives are obtained (in red). An average of 0.4 hours is required to generate the DFT spectra in the final frequency calculation on 16 cores. This figure is also shown in the main article as **Figure 5B**, but is reprinted here for ease of comparison.

Figure S2. Match scores for the twelve initial compounds, calculated as pairs of molecules (“dimers”), with r²SCAN-3c in gas phase. A sizable improvement in spectral correlation can be observed. An average of 3.0 hours is required to generate the DFT spectra in the final frequency calculation on 16 cores. This figure is also shown in the main article as **Figure 5C**, but is reprinted here for ease of comparison.

Figure S3. Match scores for the twelve initial compounds, calculated as four molecules (“tetramers”), with r²SCAN-3c in gas phase. Some correlation scores go down, which we hypothesize is because a complete conformational search for the position of 4 discrete molecules is harder to achieve, or the optimal conformer changes with the number of molecules modeled. An average of 14 hours is required to generate the DFT spectra in the final frequency calculation on 16 cores, which in the context of routine analysis we consider too high for molecules of this size.

Main article molecule number: **7-tetramer (Fig. S3)**

Name: Hymecromone

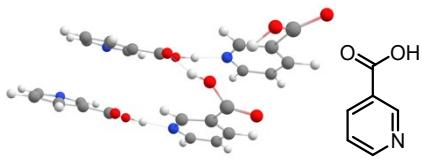

Qty of copies of the molecule modelled: 4

Qty of imaginary frequencies: 0

Final single point energy (Eh): -2445.94062319554

6. Synthesis of Borneol/Isoborneol

To a solution of (+)-Camphor (9.9mg, 0.065mmol) in MeOH (0.5mL) at room temperature is added NaBH4 (1eq, 2.5mg). The resulting mixture was stirred for 1hour (monitored by TLC). After completion, 1mL of saturated aqueous solution of NH4Cl was added followed by a dimethyl ether extraction (3x5mL). The organic layers were combined and washed with Brine and dried. Solvent removal in vacuo and column chromatography (8 : 2 Hexane : AcOEt) of the residue afforded the respective alcohols.

Isoborneol/borneol : white solid; m.p. 195,8°C; ¹H NMR (300 MHz, CDCl₃): d=0.81 and 0.84 (2 s, 3H), 0.86 (s, 3H), 0.92 (s, 3H), 1.27–1.38 (m, 3H), 1.62–1.78 (m, 2H), 1.86 (s, 1H), 2.03–2.08 (m, 1H), 2.27–2.36 (m, 1H), 3.43–3.61 (isoborneol) and 3.95–3.97 ppm (borneol) (two m, 1H); ¹³C NMR (75 MHz, CDCl₃): d=11.3, 13.3, 18.6, 20.0, 20.4, 25.8, 27.2, 28.2, 29.6, 33.8, 38.9, 40.3, 45.0, 46.3, 48.9, 49.4, 77.3, 79.8 ppm.

7. Measurement parameters

All the solid powders were placed on a quartz surface and measured using the 50X objective of a Renishaw inVia confocal Raman microscope. Bi-weekly calibration of the wavenumber axis using an internal sample of crystalline silicon ensures proper positioning of the Raman peaks. The 532 nm laser has a maximum power of 50 mW, and the 785 nm laser, of 300 mW.

Table S2. Instrumental parameters for the measurement of Raman spectra

8. SARA Compression function

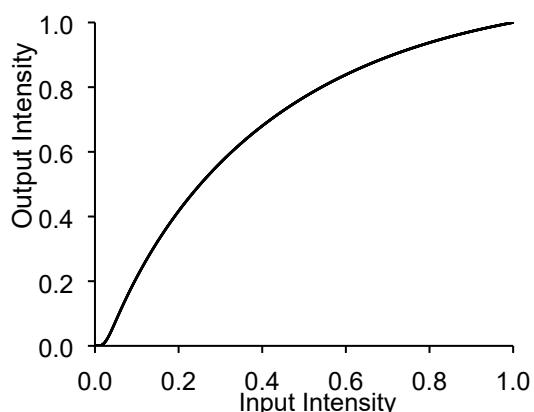

Figure S4. Intensity compression curve used by SARA in the course of its spectral pre-processing.

$$y = 1 - 1.16 (5x + 1.1)^{-0.7(x+1)} + 0.11(46^{-350x^2} - 9.8x - 0.0686)$$

The compression function is implemented in SARA by generating 2000 equally-spaced points along equation (S1) and normalizing each axis with the widely known min-max normalization to ensure that the mapping points are correctly set up from 0 to 1, meaning all spectra have a similar intensity range.

The resulting points shown in **Figure S4** are used by interpolating the spectral input intensity to the corresponding output intensity. The high resolution of the compression curve (2000 points) ensures that no noise is introduced during interpolation.

9. SARA Voigt profile adjustment and DFT functional anharmonic correction

9.1. Voigt Profile adjustment for peak width

Not all DFT software packages which calculate Raman peaks apply peak broadening to generate human-readable spectra. For instance, Gaussian is known to do so, and ORCA has a command line which can generate gaussian-shaped peaks. The SARA software is made with this in mind and will apply an empirically optimized Voigt function to each “datapoint coordinate”-type peak that the ORCA DFT package outputs. The carefully adjusted Voigt profile should generate Raman spectra with strong similarity to those obtained experimentally in most cases. However, in the event that the Raman instrument used produces spectra of drastically different peak width to what the theoretical spectra look like, a variable in the software can be changed to affect the peak width of theoretical spectra.

On line 107 of SARA.py:

```
def gen_from_peaks(data, half_width: int = 60):
```

The numerical value – established at 60 by default - can be changed to a value between 50 and 70. Empirical trial will be necessary to ensure close resemblance between the new peak width and what the chemist sees on their experiment spectra.

9.2. DFT functional anharmonic correction factor of the wavenumbers

Harmonic calculations of molecular frequencies with DFT functionals typically require an anharmonic correction. The amplitude of the scaling factor will change according to the level of theory employed. For this article, r²SCAN-3c had no strongly established correction factor, and 0.98 was used to good effect.

For the chemists who wish to try future levels of theory, the SARA program provides a simple way to change this correction factor.

On line 648 of SARA.py:

```
corrFactor = 0.98 # Anharmonic correction factor, applied on all theoretical frequencies
```

This numerical value can be changed to the appropriate anharmonic correction factor.
