## Supplementary Notes

1. Supplementary experiment on materials extrapolation to hit five extreme targets except for MW and DRD2. This note describes a supplementary experiment to the section in the manuscript: Materials extrapolation to hit multiple extreme target properties. Here, we conducted an experiment to generate molecules that hit five target properties: calculated octanol-water partition coefficient $(\log P)^{1}$, topological polar surface area $(T P S A)^{2}$, quantitative estimates of drug-likeness (QED) ${ }^{3}$, number of hydrogen bond acceptor (HBA), number of hydrogen bond donor (HBD). In this experiment, molecular weight (MW) and drug activity or dopamine receptor D2 (DRD2) ${ }^{4}$ which caused problems in the performance evaluation were excluded. Here, MOSES ${ }^{5}$ data sets were used for the training and test of $\mathrm{GCT}^{6}$. The training data contains $1,584,664$ molecules and the test data contains 176,074 molecules. PubChem ${ }^{7}$ anticancer set, which covers a wider range than the MOSES data sets, was adopted to select extrapolated targets M1 to M10 (Supplementary Figure 1a). Targets M1 to M5 were selected from anticancer samples deviating from the TPSA- $\log \mathrm{P}$ distribution of the training data and targets M6 to M10 were selected from samples deviating from the TPSA-QED distribution.

Before conducting the materials extrapolation, we evaluated the original target-hitting performance for GCT on the MOSES test data set whose distribution is similar to the trained data. To this end, the root mean squared error of each target property $i\left({ }^{R M S E}{ }_{i}\right)$ for GCT was analysed to set the target bound of the target property ${ }^{i}$ as $\pm R M S E_{i}$ (Supplementary Table 5).

The experimental results on materials extrapolation and interpolation are depicted in Supplementary Figure 1. Since the number of attempted molecular generation for materials interpolation and extrapolation is not the same, we rescaled the results based on 10,000 trials for easy comparison. The results are summarized in the left-hand side of Supplementary Figure
lb. In the experiment of materials interpolation, GCT discovered 5,365 five target-hitting molecules out of 10,000 trials for materials interpolation (target M0 in Supplementary Figure 1b). However, GCT failed to discover the five target-hitting molecules for all extrapolated targets, except for only six trials for the target M9-which is the closest target from the trained region. In contrast, AI-driven combinatorial chemistry worked well on materials extrapolation. It generated target-hitting molecules for all the extrapolated targets except the target M6. We believe that the cause lies in the way the fragments set was constructed. The x-makers shown in Supplementary Figure 1c denote the MWs of the reference molecules for the target M1 to M10. The other o-markers denote the MWs of molecular fragments constituting the fragments set. The problem is that the MW of the target M6 is $167 D a$. It is significantly smaller than the other MWs of extrapolated targets. Note that the $\log$ P, TPSA, HBA, and HBD are scores that are calculated by summing each score of molecular fragments constituting the molecule. Hence, the descriptors have very large correlations with molecular size. It means that it is highly correlated with MW. Therefore, the combinations of properties are likely to be found only in materials with a certain level of MW. Since the MW of $167 D a$ is a level that can be composed of one or two molecular fragments in the fragments set, it might be difficult to complete target-hitting materials with a randomly selected initial fragment. In addition, the reference molecule of the target M6 was the only molecule that are not completely fragmented into molecular fragments with the used fragments set. Therefore, the fragment set should be designed with smaller fragments if the targets are smaller.
2. Size of the fragment set. We selected the size of the fragment set according to the result of the performance benchmark. To this end, we trained our model with various sizes of the fragment sets on a randomly sampled target (MW: 321.35, logP: 0.653, QED: 0.830, TPSA:
73.74, HBA: 4, HBD: 1). By subsampling BRICS $^{8}$ 40k fragments in the order of their appearance in the MOSES database ${ }^{5}$, eight fragment sets with various sizes were constructed: $\sim 40 \mathrm{k}$ fragments $(41,153), \sim 20 \mathrm{k}$ fragments $(21,477), \sim 12 \mathrm{k}$ fragments $(12,768), \sim 8 \mathrm{k}$ fragments $(8,835), \sim 6 \mathrm{k}$ fragments $(6,434), \sim 2 \mathrm{k}$ fragments $(2,547), \sim 0.5 \mathrm{k}$ fragments $(565), \sim 0.2 \mathrm{k}$ fragments (166).

To select the efficient size of the fragment set, we compared the ratio of unique molecules after generating 3,000 molecules with the various fragment sets. As the results, we confirmed that the uniqueness ratio according to the size of the fragment sets as follows: $\sim 40 \mathrm{k}$ fragments (98.87\%), ~20k fragments (96.1\%), ~12k fragments (93.73\%), ~8k fragments (90.87\%), ~6k fragments ( $88.47 \%$ ), $\sim 2 \mathrm{k}$ fragments ( $74.7 \%$ ), $\sim 0.5 \mathrm{k}$ fragments ( $38.83 \%$ ), and $\sim 0.2 \mathrm{k}$ fragments (16\%). In addition, we compared the rewards achieved for each size of the fragment set (Supplementary Figure 2). Considering both results of the uniqueness ratio and the reward, we decided to use a fragment set with a size of around 2 k .

More precisely, we used a fragment set of 2,207 BRICS fragments which appear more than 100 times in the curated ChEMBL training dataset ${ }^{4}$ for the experiments in the manuscript. In the case of the supplementary experiment (Supplementary Note 1), we used a fragment set of 2,547 BRICS fragments which appear more than 150 times in the MOSES training dataset ${ }^{5}$.
3. Benchmark on reinforcement learning algorithms and action masking. There are many kinds of algorithms in reinforcement learning. We benchmarked the performance of state-of-the-art RL algorithms on our materials extrapolation problem. In addition, we benchmarked performance according to whether or not action masking was applied. To this end, we introduced a scoring metric as follows:

$$
\text { Score }=\sum_{y \in \text { prop. }} \frac{100}{\frac{y_{\text {gen. }}-y_{\text {trg. }} \mid}{R M S E_{y}}+1}
$$

where $y_{\text {gen. and }} y_{\text {trg. denote the value of generated molecule's property }} y_{\text {and the value of the }}$ target property $y$, respectively. Here, prop. is a set of $\log$ P, TPSA, QED, HBA, HBD, and MW. We calculated the average score for 10,000 molecules generated by each algorithm. The results are shown in Supplementary Figure 3. As shown in the results, the proximal policy optimization (PPO) ${ }^{9}$ algorithm with action masking showed the best performance for our problem. Hence, we used the PPO algorithm with action masking to train our models.
4. Parameter setting for QuickVina2. Configuration for molecular docking simulation with QuickVina2 ${ }^{10}$ is summarized in Supplementary Table 6. Here, the concept of exhaustiveness factor is similar to the concept of the population of the genetic algorithm. As the value of the exhaustiveness factor increases, the possibility of deriving an accurately optimized conformation increases. However, as the value of the exhaustiveness factor increases, the calculation time increases linearly. Hence, a strategy of the step increase for the exhaustiveness factor was adopted. The exhaustiveness factor is initially set to 1 , and if two or more molecules with a docking score less than -12.5 are generated, the value is set to 2 . Thereafter, if two or more of the generated molecules' docking scores are less than -14, the exhaustiveness factor is set to 4 . After that, if two or more molecules with a docking score less than -15.5 are generated, the value is set to 8 .
5. Active molecules of protein docking problem. As a result of generating 10,000 molecules with a low docking score for the $5-\mathrm{HT}_{1 \mathrm{~B}}$ receptor, 23 molecules matched the molecular
structure present in the ChEMBL ${ }^{11}$ database. When investigating their pharmaceutical activity in the PubChem Bioassay database ${ }^{7}$, five out of the 23 molecules ( $21.7 \%$ ) were the molecules that have been reported as pharmaceutically active molecules for specific targets. Except for the CHEMBL1726441 which is stated in the manuscript, the detailed information for the active molecules is described in Supplementary Table 7.

When analyzing the ratio of pharmaceutical activity for a set of 10,000 randomly sampled molecules from the ChEMBL ${ }^{11}$ database, it was $9.6 \%$ ( 961 out of 10,000 molecules); we achieved $21.7 \%$ (five out of 23 molecules). Considering the above results, we believe that some of the generated molecules whose drug activity is identified may also have potential medicinal effects.

## 6. Determination of the maximum number of fragments to use in HIV-related targets. Of

 the all cases, we limited the maximum number of fragments to less than six. This is because the total molecular weight of the generated molecule becomes too large to be used as a drug if a greater number of fragments is used. In general, a molecule with a molecular weight between 200 and $600 D a$ is used for drugs ${ }^{12}$. Note that the average molecular weight of the fragments constituting the fragment set is about $110 D a$. Therefore, if more than six fragments are used, it may be too large for a drug. The predicted $\mathrm{pIC}_{50}$ values for three HIV-related targets are summarized in Supplementary Table 8.7. Model accuracy of prediction model. For the experiment on Materials extrapolation to hit multiple extreme target properties, 7 target properties were considered: $\log \mathrm{P}$, TPSA, QED, HBA, HBD, MW, and DRD2 activity. All properties except for DRD2 activity were calculated
using RDKit. Using RDKit, HBA, HBD, and MW are values that are directly calculated once the molecule is defined, while $\log P$ is computed based on the Wildman-Crippen method ${ }^{1}$, and TPSA is determined using the summation of fragment contributions ${ }^{2}$. RDKit calculates the Quantitative Estimation of Drug-likeness (QED) using a method that considers $\log$ P, TPSA, HBA, HBD, and MW. Lastly, DRD2 activity is predicted using the QSAR model introduced in the reference paper ${ }^{4}$ which is made using the support vector machine classification model. According to the reference paper, the QSAR model performance on active molecules of the test set shows that it misclassifies $10 \%$ of all cases as inactive.

For the Application to the discovery of protein docking molecules, QVina2 was used to predict the docking score of a molecule. In terms of model accuracy, it can depend on the specific target and parameter used in the program. Compared to Vina, it has Pearson's correlation coefficient(r) of 0.967 , and the comparison of predicted binding energy can be seen in the reference paper ${ }^{10}$.

For the Application to discovery of HIV inhibitors, the QSAR model from the reference paper was used, which aims to predict the pIC50 value of each HIV-related target. The performance of the model can be found on the ESI $\dagger$ Table S10, which was analyzed from the reference paper ${ }^{13}$.

Based on the accuracy of the evaluation model, it is possible to narrow down the candidates more precisely within the chemical space that one aims to explore. Hence, the accuracy of evaluators affects how precisely narrow down the search space.

## Supplementary Figures

## Supplementary Figure 1. Results for a supplementary experiment to generate the five

 target-hitting molecules. a, Distribution of MOSES ${ }^{5}$ training set and the extrapolation targets M1 to M10. b, Results comparison of AI-driven combinatorial chemistry and GCT. The left table shows the number of molecules that hit the target bounds. Each blue-red line in the right parallel coordinates plot indicates a molecule within the target bounds (green) of $\log \mathrm{P}$, TPSA, QED, HBA, and HBD at the same time. Blue-red lines were colored according to the log-scale score. The yellow line indicates each target. c, MW distribution of fragments in the fragments set and extrapolated targets. d, A molecular generation path example for target M2.

Supplementary Figure 2. The performance by the number of fragments constituting a fragment set. The fragment set consists of the fragments derived from the MOSES dataset. 3,000 molecules were generated with various sizes of fragment sets, and a box plot was drawn for unique molecules. The mean reward for each outcome is represented numerically, while the box is set with percentiles 25 and 75 , and the whiskers extend to the $5^{\text {th }}$ and $95^{\text {th }}$ percentiles.

Supplementary Figure 3. Benchmark results for model performance. a, Results according to the type of reinforcement learning algorithms. $\mathbf{b}$, Results according to the presence of action masking.

Supplementary Figure 4. The learning curve of the model. The graph illustrates changes in rewards according to training iterations.

Supplementary Figure 5. The performance by the number of fragments used for HIV inhibitor discovery. For 10,000 generated molecules for each case, $\mathrm{pIC}_{50}$ for each case was compared by setting the maximum fragments from 4 to 9 . The mean of predicted $\mathrm{pIC}_{50}$ value for each outcome is represented numerically, while the box is set with percentiles 25 and 75, and the whiskers extend to the $5^{\text {th }}$ and $95^{\text {th }}$ percentiles.

Supplementary Figure 6. Synthetic Accessibility (SA) score of each experiment. a, Materials extrapolation to hit multiple extreme target properties. b, Application to the discovery of protein docking molecules. c, Application to discovery of HIV inhibitors. The mean SA score for each outcome is represented numerically, while the box is set with percentiles 25 and 75 , and the whiskers extend to the $5^{\text {th }}$ and $95^{\text {th }}$ percentiles.

Supplementary Table 5. ${ }^{R M S E}{ }_{i}$ for materials interpolation for the MOSES database with GCT.

| Property $i$ | $R M S E_{i}{\text { for } \text { GCT }^{6}}{ }^{\text {}}$ |
| :--- | :--- |
| $\operatorname{logP}$ | 0.214 |
| TPSA | 3.225 |
| QED | 0.037 |
| HBA | 0.180 |
| HBD | 0.106 |

Supplementary Table 6. Parameter settings for QuickVina2.

| Parameter | Configuration |
| :--- | :--- |
| Exhaustiveness | Changes over time, from 1 to 8 |
| Modes | 10 |
| CPU per subprocess | 1 |
| Box center | $-26.602,5.277,17.898$ |
| Box size | $22.5,22.5,22.5$ |

# Supplementary Table 7. The structure and role of molecules found to be active in the database among the molecules generated through our methodology. 

| Target Name |
| :--- |

Supplementary Table 8. The $\mathrm{pIC}_{50}$ comparison by the number of fragments of $\mathbf{3 , 0 0 0}$ generated molecules of each termination conditions. The case of showing the best performance for each condition is indicated in blue bold text.

| Steps | CCR5 |  | INT |  | RT |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | maximum | median | maximum | median | maximum | median |
| $\mathbf{4}$ steps | 8.81 | 7.75 | $\mathbf{7 . 2 9}$ | $\mathbf{6 . 6 2}$ | 7.91 | 7.26 |
| $\mathbf{5}$ steps | 8.93 | 8.20 | 7.10 | 6.42 | 7.94 | $\mathbf{7 . 3 6}$ |
| $\mathbf{6}$ steps | 9.05 | 8.51 | 7.06 | 6.28 | 7.84 | 7.28 |
| $\mathbf{7}$ steps | $\mathbf{9 . 3 1}$ | $\mathbf{8 . 5 7}$ | $\mathbf{7 . 2 9}$ | 6.42 | 7.92 | 7.35 |
| $\mathbf{8}$ steps | 9.12 | 8.42 | 7.10 | 6.39 | 7.77 | 7.22 |
| $\mathbf{9}$ steps | 9.11 | 8.44 | 7.28 | 6.40 | 7.81 | 7.07 |

Supplementary Table 9. Comparison with other methods. We compared our model against a few other models. The best case in each section was marked in blue bold. Our proposed model has produced compounds with the highest maximum $\mathrm{pIC}_{50}$ scores in two of the three domains, demonstrating that it outperforms others. The benchmark results of GCPN ${ }^{24}$, JT-VAN ${ }^{25}$, $\mathrm{MSO}^{26}, \mathrm{PGFS}^{27}$ were borrowed from ref. ${ }^{27}$.

| Method | CCR5 | INT | RT |
| :---: | :---: | :---: | :---: |
| GCPN $^{\mathbf{2 5}}$ | $8.20(8.62)$ | 6.45 | $7.42(7.45)$ |
| JT-VAE $^{\mathbf{2 6}}$ | $8.15(8.23)$ | 7.25 | 7.58 |
| MSO $^{\mathbf{2 7}}$ | $8.68(8.77)$ | 7.28 | 7.76 |
| PGFS $^{\mathbf{1 3}}$ | 9.05 | $\mathbf{7 . 5}$ | 7.89 |
| RL $($ Ours $)$ | $\mathbf{9 . 1 1}$ | 7.17 | $\mathbf{8 . 0 1}$ |

Supplementary Table 10. Performance evaluation of trained QSAR models for predicting HIV-related targets using cross-validation ${ }^{13} . R^{2}$ refers to coefficient of determination, MAE refers to mean absolute error, and Range refers to range of the values in the dataset.

| Dataset | $\mathbf{R}^{2}$ |  | MAE |  | Range |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | aggregated | average | aggregated | average |  |
| CCR5 | 0.72 | $0.69 \pm 0.03$ | $\mathbf{0 . 5 1}$ | $0.54 \pm 0.02$ | $4.04-10.30$ |
| HIV-INT | 0.69 | $0.65 \pm 0.04$ | 0.45 | $0.48 \pm 0.03$ | $4.00-8.15$ |
| HIV-RT | 0.55 | $0.52 \pm 0.05$ | 0.51 | $0.53 \pm 0.03$ | $4.00-8.66$ |
