## I. Experimental Part

### S1 Experimental procedures

Nickel(II) perchlorate hexahydrate ( $\text{Ni}(\text{ClO}_4)_2 \times 6\text{H}_2\text{O}$ ), Cobalt(II) chloride hexahydrate ( $\text{CoCl}_2 \times 6\text{H}_2\text{O}$ ), Iron(II) perchlorate hydrate ( $\text{Fe}(\text{ClO}_4)_2 \times \text{H}_2\text{O}$ ), Manganese(II) chloride tetrahydrate ( $\text{MnCl}_2 \times 4\text{H}_2\text{O}$ ) and 4,6-Dihydroxy-1,3,5-triazine-2-carboxylic acid potassium salt (Oxonic acid potassium salt) were purchased from Sigma-Aldrich and used as received. Distilled water was further purified using a Milli-Q Ultrapure water purification system. Metal analyses were performed with a Varian 700-ES series inductively coupled plasma-optical emission spectrometer (ICP-OES).

### S2 Powder X-Ray Diffraction

Powder X-ray diffraction (PXRD) patterns were collected with the Cu-K $\alpha$  radiation on a Bruker D8 Advance diffractometer, equipped with a Lynxeye XE-T detector. The long fine focus (LFF) tube was operated at 40 kV and 40 mA. To minimize preferred orientations of the microcrystals, the samples were carefully side-loaded onto a zero-background sample holder. Unit cell parameters were determined by the N-Treor program operating within the EXPO2014 software.<sup>1</sup> Indication of possible space groups was obtained by the same EXPO software, which confirmed those found in the literature. Rietveld refinement procedures were performed with the help of the GSAS-II package.<sup>2</sup> The refinement involved unit cell parameters, positional atomic coordinates, background, and peak profile parameters. Atomic displacement factors were set to the literature values and were not refined. Soft constraints were adopted for light atoms to avoid unrealistic bond distances and angles. The statistical weight of these constraints was slowly decreased during the refinement procedure. Atomic positions and site occupancy factors of water molecules were not refined. At the end of the refinement, the shifts in all parameters were less than their standard deviations. **Table S1** resumes the main crystallographic data of the analyzed samples, while **Figure S1** shows the related final Rietveld plots.

**Figure S1.** Final Rietveld plots for **(cis)-CoCo**, **(trans,cis)-NiNi** and **(trans,cis)-NiMn**, reporting the observed pattern (blue symbols), the calculated pattern (green line), and their difference (cyan line). Blue markers at the bottom indicate the calculated positions of peaks.

**Table S1.** Main crystallographic data of the analyzed samples. The structures of all samples were found to have a tetragonal symmetry.

<sup>(a)</sup> refined with the Rietveld method; <sup>(b)</sup>  $R_{wp} = [\sum w(Io - Ic)^2 / \sum wIo^2]^{1/2}$ ; <sup>(c)</sup>  $\chi^2 = [\sum w(Io - Ic)^2 / (No - Nvar)]^{1/2}$ ;

<sup>(d)</sup>  $M_{20} = Q_{20}/(2N_{20}|\Delta Q|_{avg})^3$

### S3 Synthesis of CPs

Homometallic **(trans,cis)-NiNi** and **(cis)-CoCo** were synthetized slightly modifying the procedure reported in the literature.<sup>4</sup> Oxonic acid potassium salt (0.50 mmol) was dissolved in 5 mL of water and heated at 70-80 °C under stirring. After its complete dissolution, Ni(ClO<sub>4</sub>)<sub>2</sub> x6H<sub>2</sub>O or CoCl<sub>2</sub> x6H<sub>2</sub>O (0.50 mmol) was added to the solution and the resulting mixture was allowed to react for 4 hours. The resulting suspension was filtered; the collected powder was washed with deionized water, ethanol, diethyl ether and dried in air for 24 h. Heterobimetallic CPs were obtained with an analogous procedure, introducing

two metal salts in the suitable proportions. **Table S2** show the reagents used for the synthesis of heterobimetallic CPs and the molar fraction of each metal ion derived by ICP.

**Table S2.** Reagents and ICP data of the synthesized heterobimetallic CPs.

CP	Metal salt (mmol)		ICP molar fraction	
<b>(cis)-CoFe</b>	CoCl <sub>2</sub> 6H <sub>2</sub> O (0.3)	Fe(ClO <sub>4</sub> ) <sub>2</sub> H <sub>2</sub> O (0.2)	Co (0.87)	Fe (0.13)
<b>(cis)-CoMn</b>	CoCl <sub>2</sub> 6H <sub>2</sub> O (0.2)	MnCl <sub>2</sub> 4H <sub>2</sub> O (0.3)	Co (0.84)	Mn (0.16)
<b>(cis)-CoNi</b>	CoCl <sub>2</sub> 6H <sub>2</sub> O (0.35)	Ni(ClO <sub>4</sub> ) <sub>2</sub> 6H <sub>2</sub> O (0.15)	Co (0.68)	Ni (0.32)
<b>(cis)-FeMn</b>	Fe(ClO <sub>4</sub> ) <sub>2</sub> H <sub>2</sub> O (0.2)	MnCl <sub>2</sub> 4H <sub>2</sub> O (0.3)	Fe (0.78)	Mn (0.22)
<b>(trans,cis)-NiFe</b>	Ni(ClO <sub>4</sub> ) <sub>2</sub> 6H <sub>2</sub> O (0.3)	Fe(ClO <sub>4</sub> ) <sub>2</sub> H <sub>2</sub> O (0.2)	Ni (0.83)	Fe (0.17)
<b>(trans,cis)-NiCo</b>	Ni(ClO <sub>4</sub> ) <sub>2</sub> 6H <sub>2</sub> O (0.35)	CoCl <sub>2</sub> 6H <sub>2</sub> O (0.15)	Ni (0.76)	Co (0.24)
<b>(trans,cis)-NiMn</b>	Ni(ClO <sub>4</sub> ) <sub>2</sub> 6H <sub>2</sub> O (0.2)	MnCl <sub>2</sub> 4H <sub>2</sub> O (0.3)	Ni (0.86)	Mn (0.14)

#### S4 Electrochemical measurements

Electrochemical measurements were performed with a Squidstat Solo potentiostat (manufactured by Admiral Instruments) using a one-compartment three-electrode cell. In all experiments, a classical electrochemical cell with a capacity of 20.0 mL equipped with a Hg/HgO (1 M NaOH) reference electrode, a platinum wire as the counter electrode and a glassy carbon working electrode was used. All measurements were carried out at room temperature without stirring using a 1 M KOH solution as electrolyte without iR-correction. The potentials reported in the work were calibrated to reversible hydrogen electrode (RHE) according to the Nernst equation: E (V vs. RHE) = E (V vs. Hg/HgO) + 0.918 V. Cyclic voltammograms (CVs) were recorded with a scan rate of 100 mV/s whereas linear scan voltammetry (LSV) was performed at a scan rate of 5 mV/s. The long-term stability of CPs was assessed

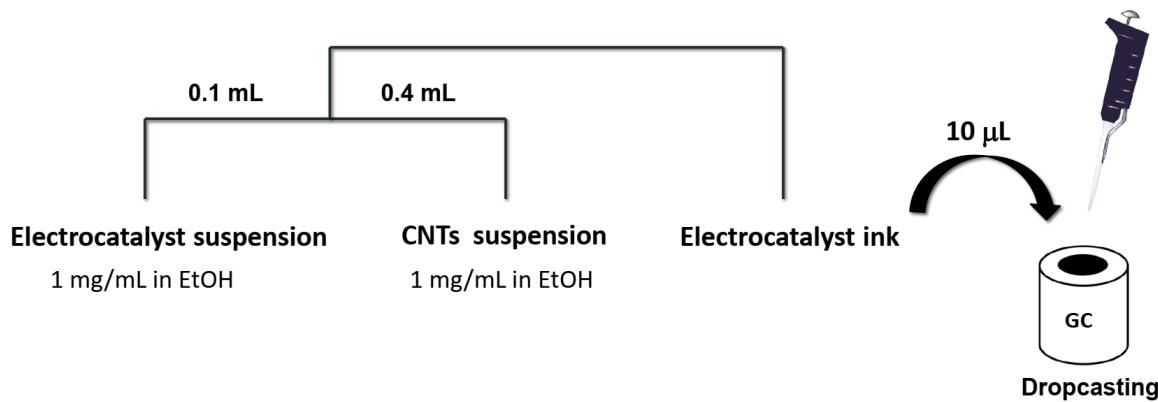

by evaluating the current decrease at 1.9 V vs RHE after 50 cycles from 0.918 to 1.918 V at 100 mV/s. The electrochemically active surface area (ECSA) was calculated using the fitted value of the double-layer capacitance ( $C_{dl}$ ) using the formula:

$$ECSA = C_{dl}/Cs$$

$C_{dl}$  was determined by recording CVs at different scan rates (5 - 100 mV/s) in a non-Faradaic region and corresponds to one-half the slope of the linear fit of the capacitive current ( $\Delta i = i_a - i_c$ ) versus scan rate plot. The specific capacitance of the electrolyte ( $C_s$ ) was taken as  $40 \mu\text{F/cm}^2$ .<sup>5</sup>

## S5 Working electrode preparation

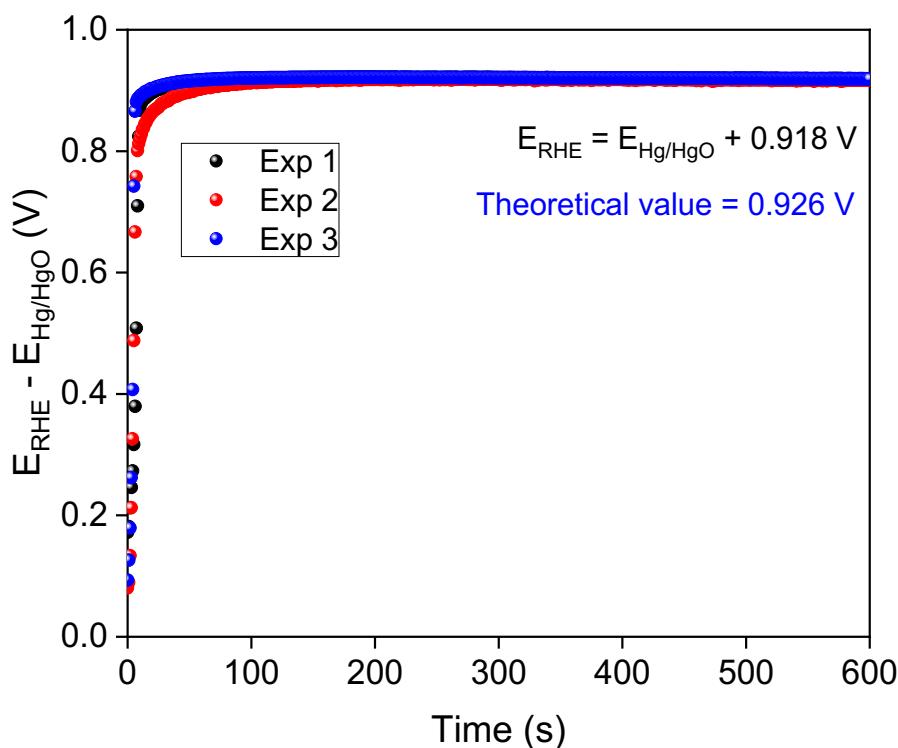

The working electrodes for the electrochemical studies were prepared as reported in Scheme S1. First, an electrocatalyst suspension was prepared by adding 1 mL of ethanol to 1 mg of CP. The resulting suspension was sonicated for 5 minutes. In parallel, a carbon nanotubes (CNTs) suspension was prepared by sonicating 5 mg of CNT in 5 mL of ethanol for 30 minutes. The electrocatalyst ink was obtained by mixing 0.1 mL of electrocatalyst suspension and 0.4 mL of CNTs suspension. Finally, 10  $\mu\text{L}$  of electrocatalyst ink was carefully drop casted onto the glassy carbon working electrode and allowed to dry in air for 4 hours.

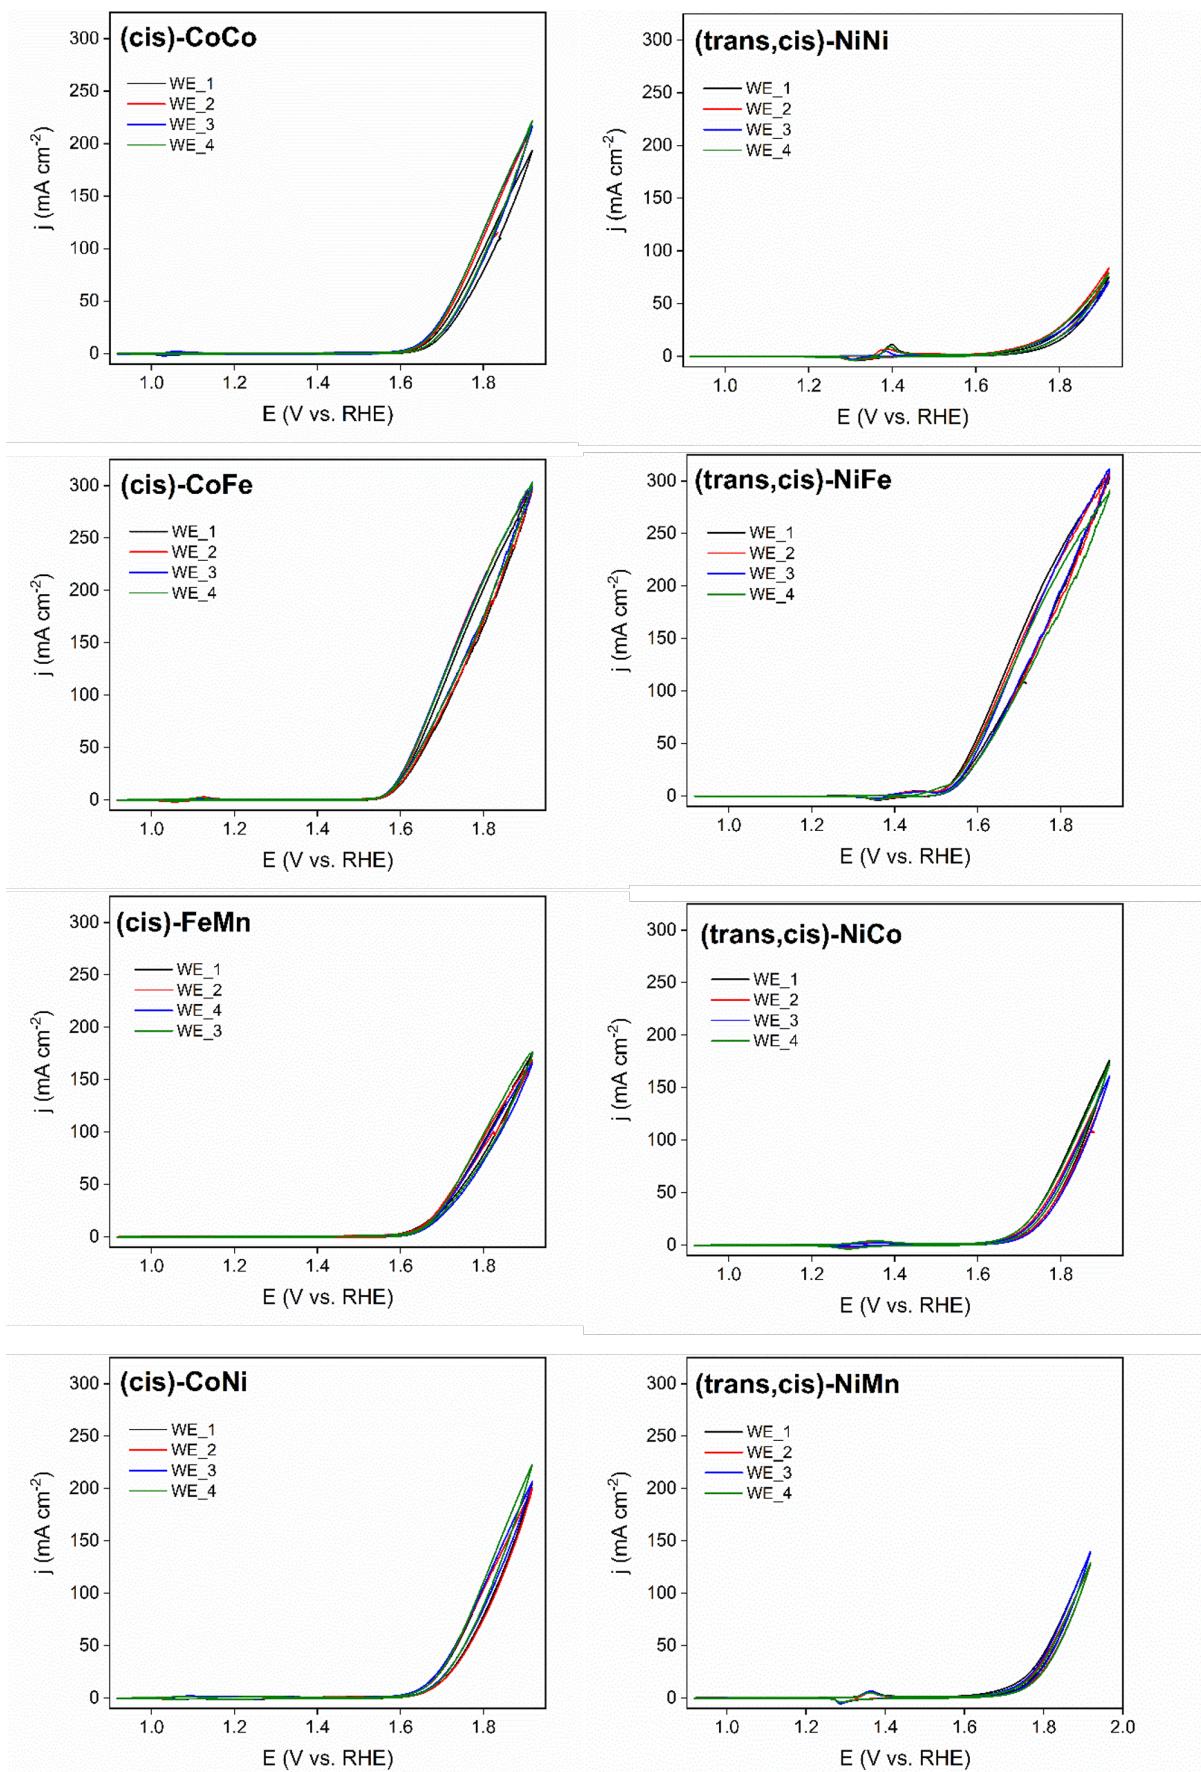

**Scheme S1.** Schematic representation of the working electrode preparation.

## S6 Reference electrode calibration

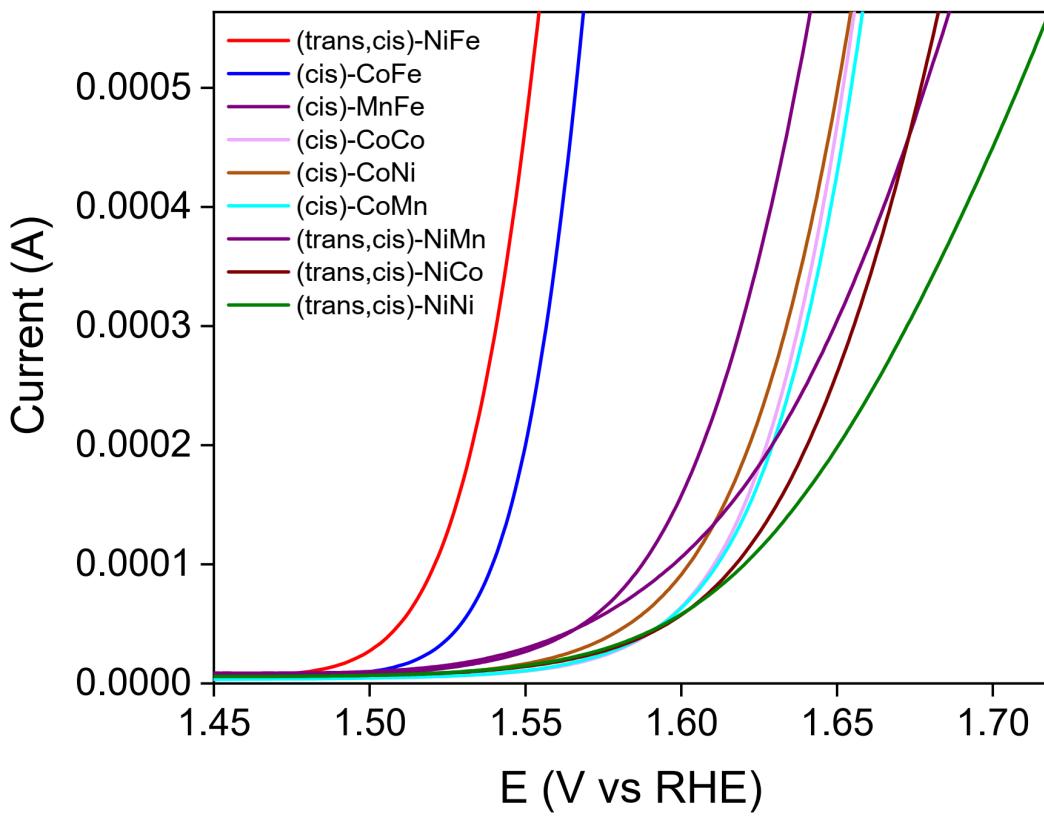

The Hg/HgO (NaOH 1M) reference electrode was calibrated with respect to reversible hydrogen electrode (RHE) by measuring the open circuit potential (OCP) between a Pt/H<sub>2</sub> working electrode and the Hg/HgO (NaOH 1 M) reference electrode. Both electrodes were immersed in the electrolyte KOH solution at pH 14 and the OCP was measured for 10 minutes (**Figure S2**). The experiment was repeated three times and an average value of 0.918 V was obtained, which is close to the theoretical value calculated by the Nernst equation (0.926 V).

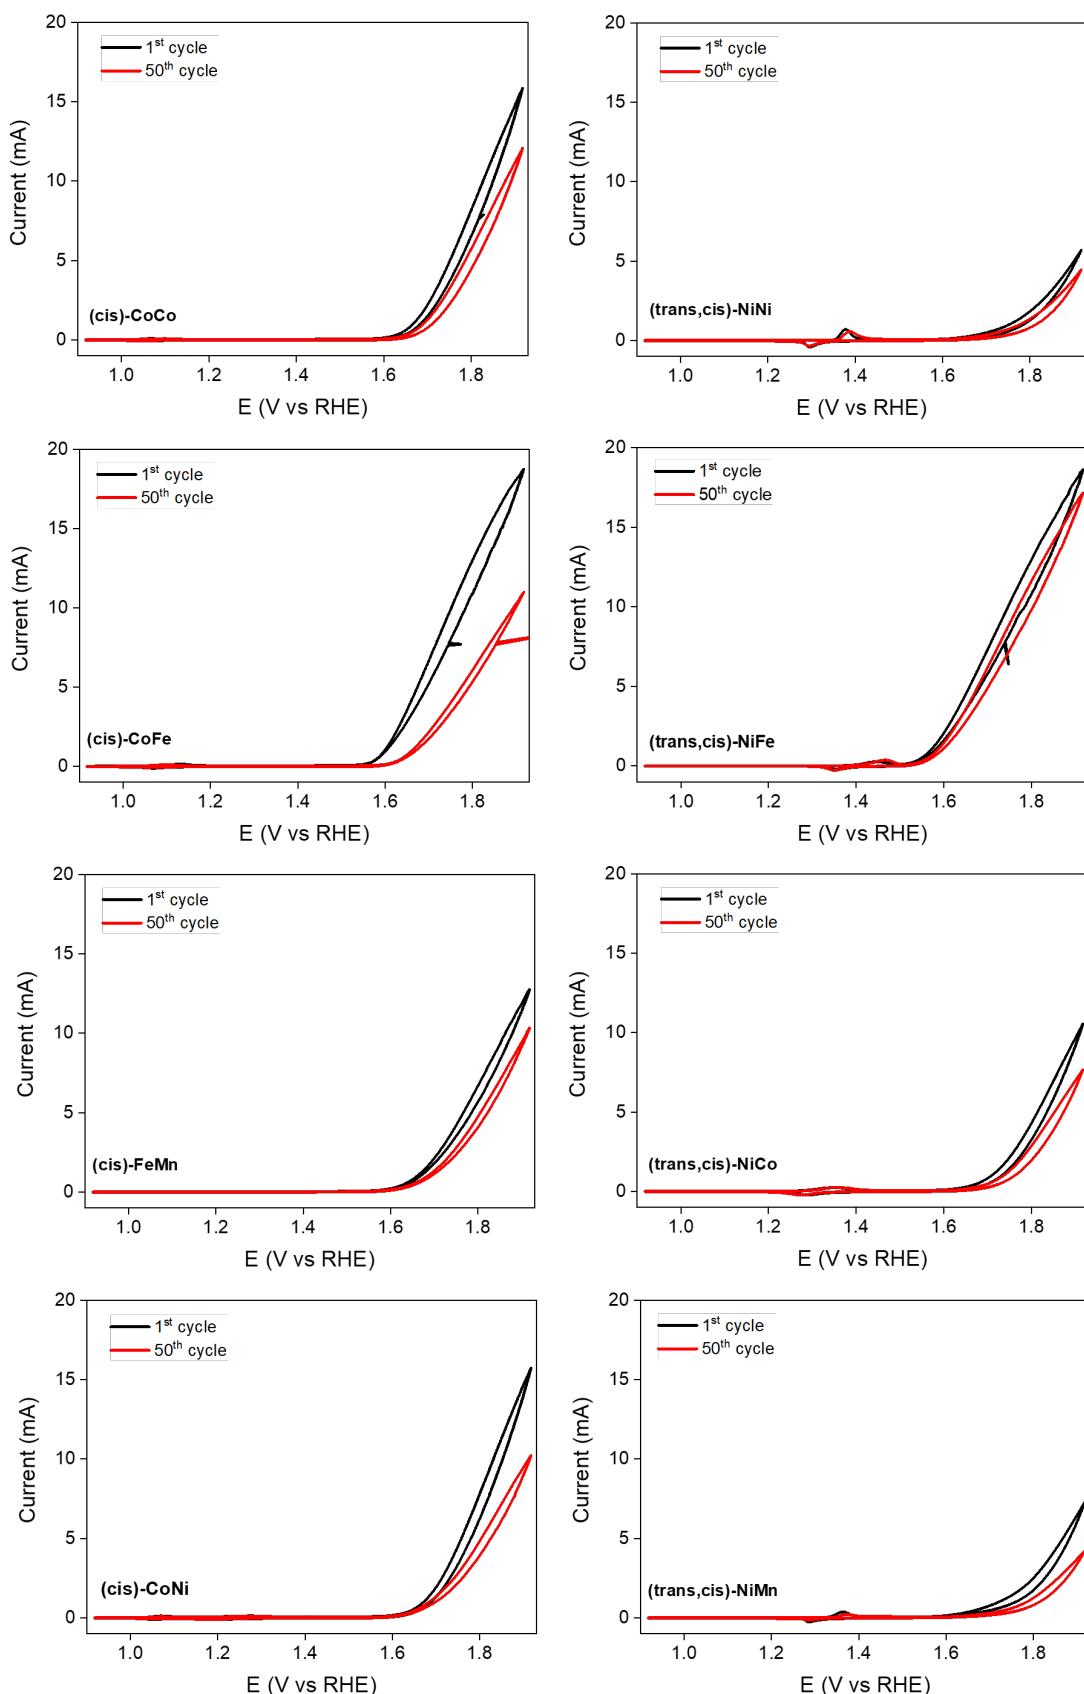

**Figure S2.** Calibration of Hg/HgO (NaOH 1M) in KOH electrolyte solution (pH = 14) with respect to RHE.

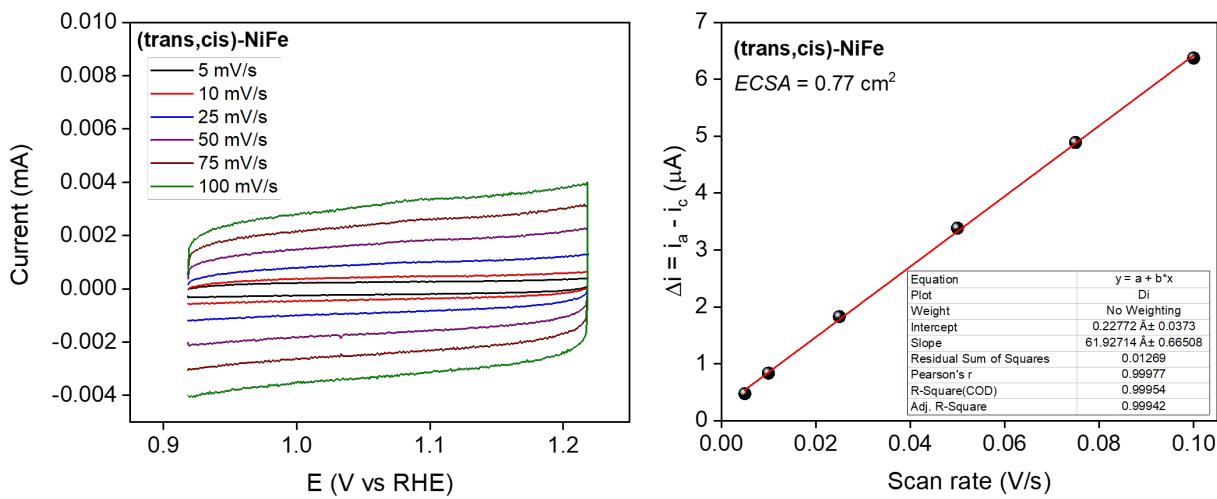

**Figure S3.** Comparison of four independently prepared working electrode (WEs) for each CP electrocatalytic system, recorded in 1 M KOH at a scan rate of 100 mV/s.

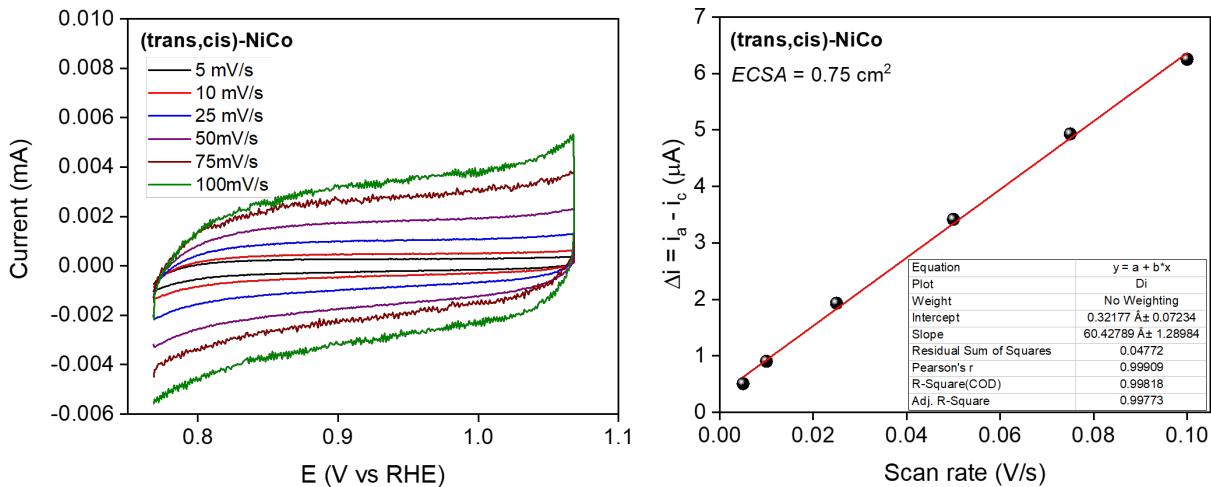

**Figure S4.** LSV curves of CPs recorded in 1 M KOH at a scan rate of 5 mV/s.

**Figure S5.** Comparison of the 1<sup>st</sup> (black) and 50<sup>th</sup> (red) cyclic voltammogram of CPs recorded in 1 M KOH at a scan rate of 100 mV/s. The gradual decrease in catalytic current indicates the limited stability of CPs under electrocatalytic conditions.

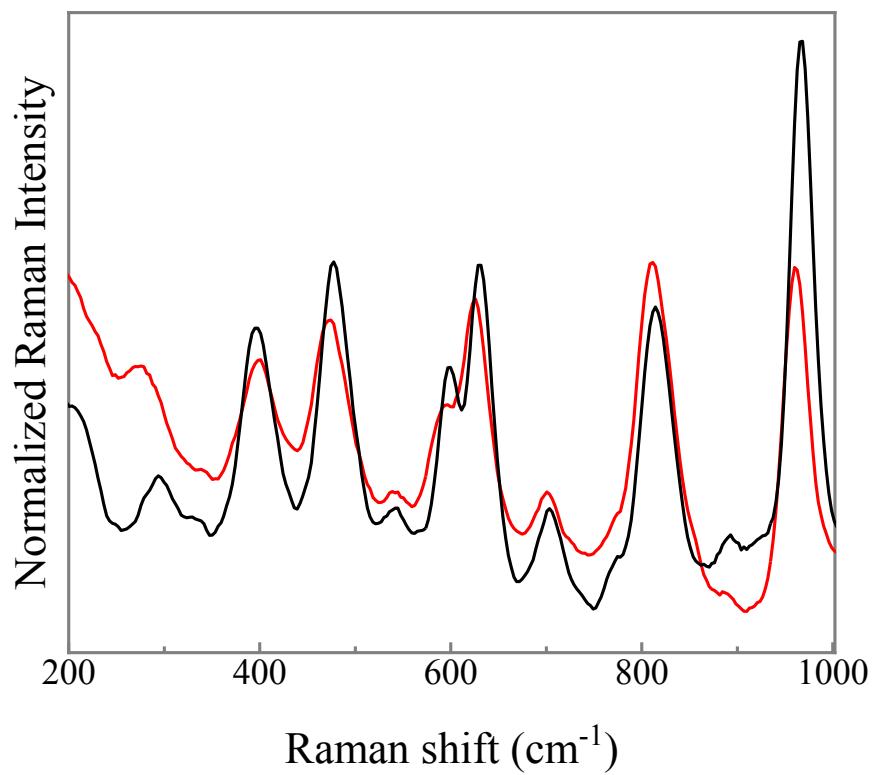

**Figure S6.** CVs of **(trans,cis)-NiFe** at the different scan rates from 5-100 mV/s (left) and the plot of the capacitive currents versus scan rate (right).

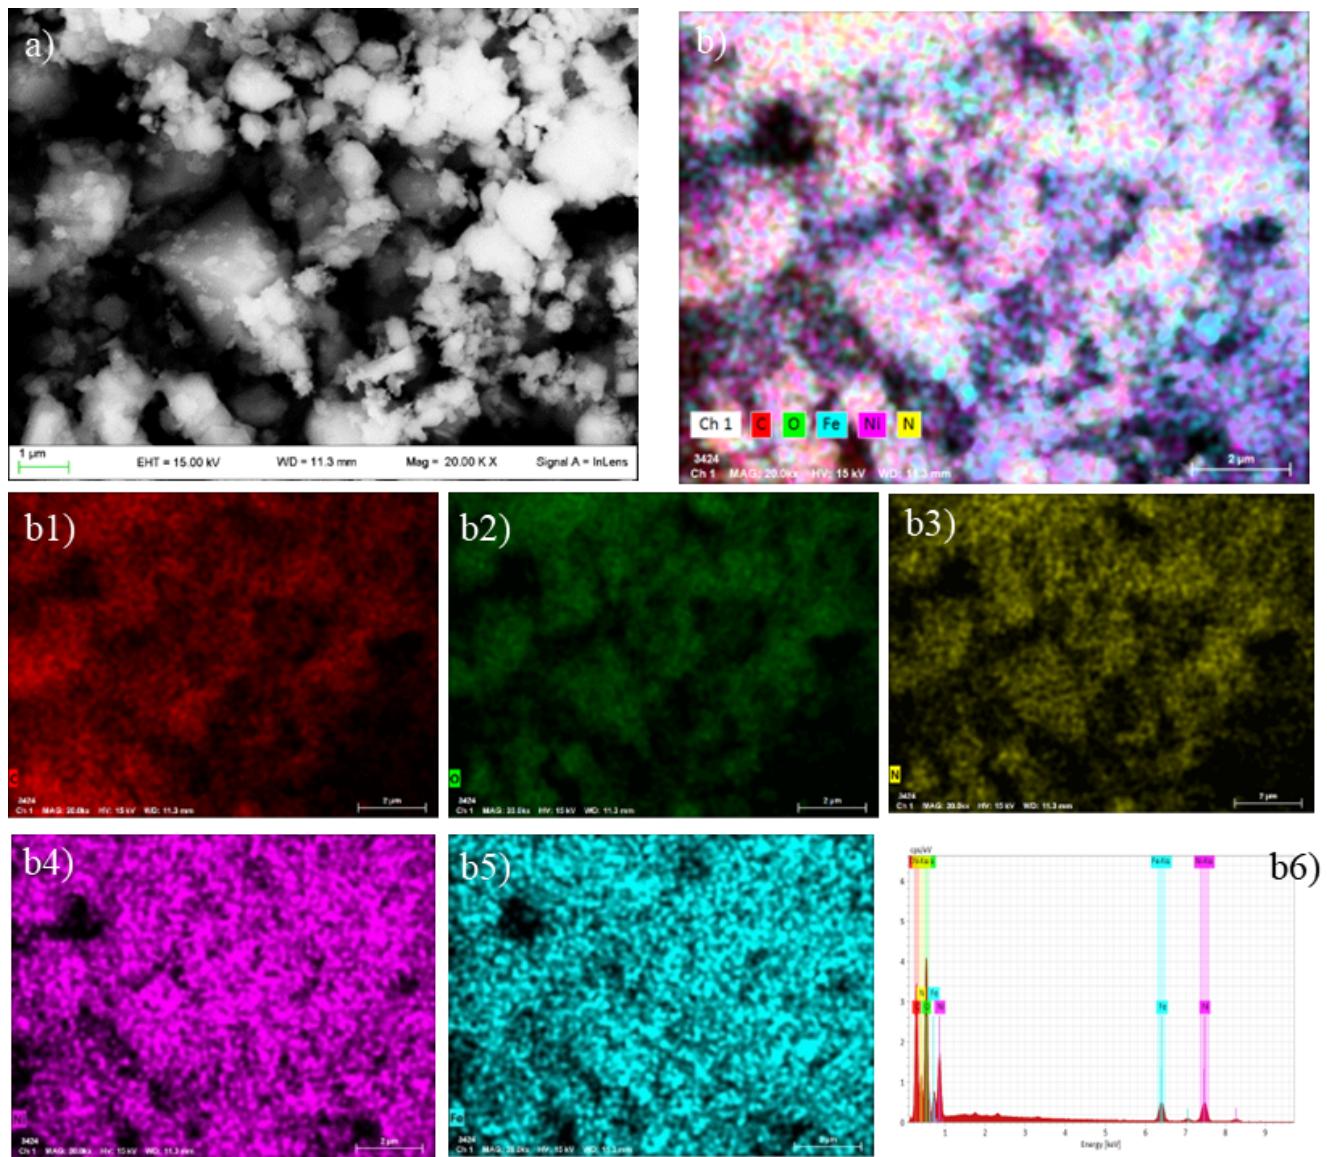

**Figure S7.** CVs of **(trans,cis)-NiCo** at the different scan rates from 5-100 mV/s (left) and the plot of the capacitive currents versus scan rate (right).

Note: As shown in **Figure S6****Figure S7**, the ECSA determined for **(trans,cis)-NiFe** ( $0.77 \text{ cm}^2$ ) and **(trans,cis)-NiCo** ( $0.75 \text{ cm}^2$ ) is substantially the same, thus the huge difference of electrocatalytic performances between theses CPs can only be attributed to their different intrinsic activity and not to the accessibility of active sites to the medium/electrolyte.

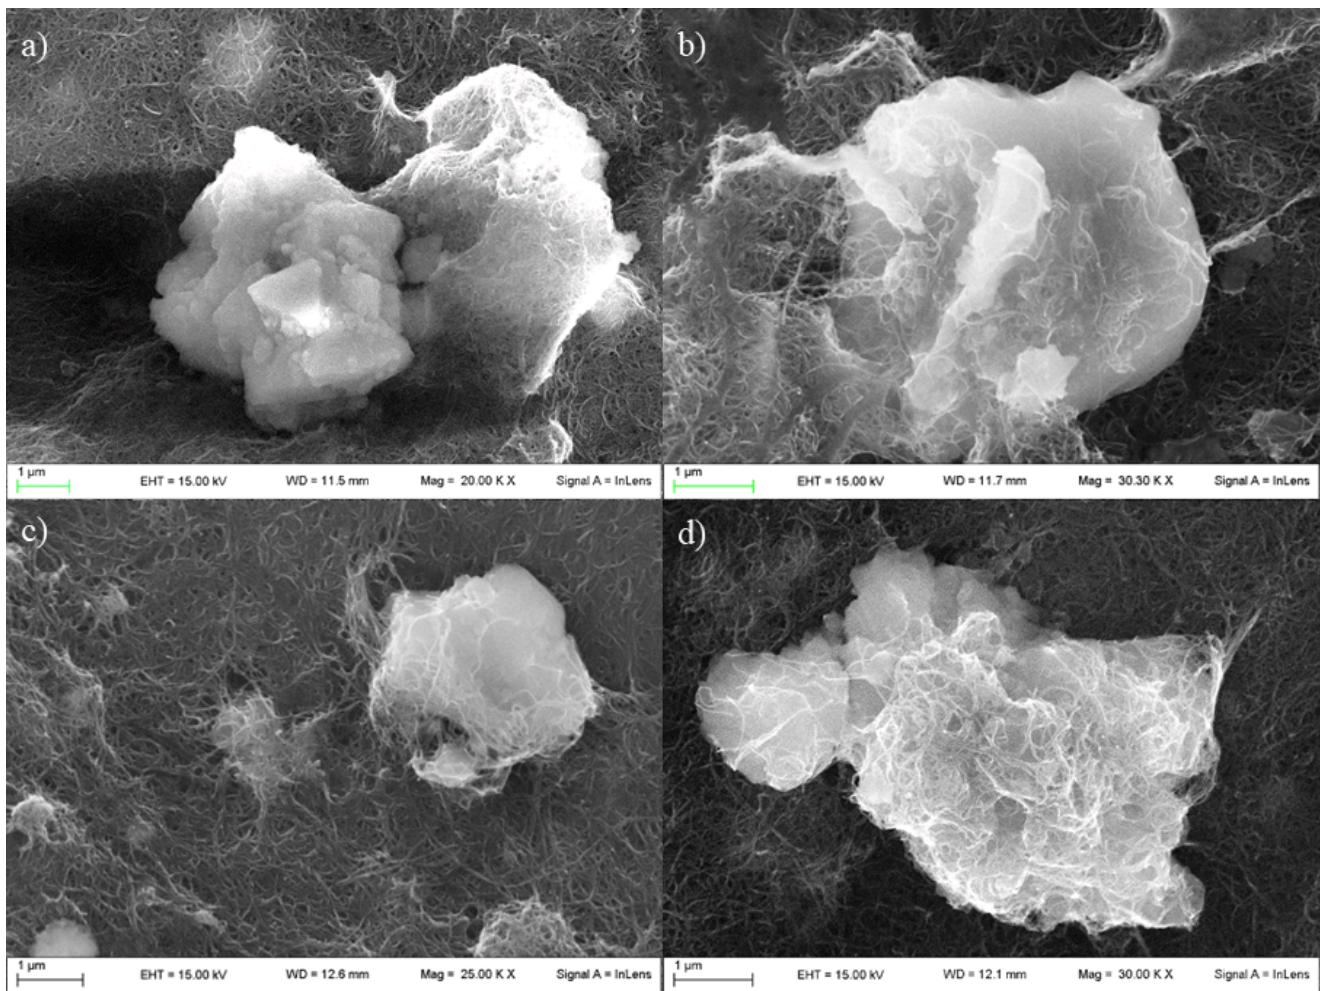

**S7 Stability evaluation via Raman, SEM and EDX analysis**

**Figure S8.** Raman spectra of **(trans,cis)-NiFe** (black line) and NTC matrix + **(trans,cis)-NiFe** untreated (red line).

**Figure S9.** a) SEM image; b) EDX mapping and elemental analysis, including b1) C; b2) O; b3) N; b4) Ni; b5) Fe; b6) elemental analysis for **(trans,cis)-NiFe**.

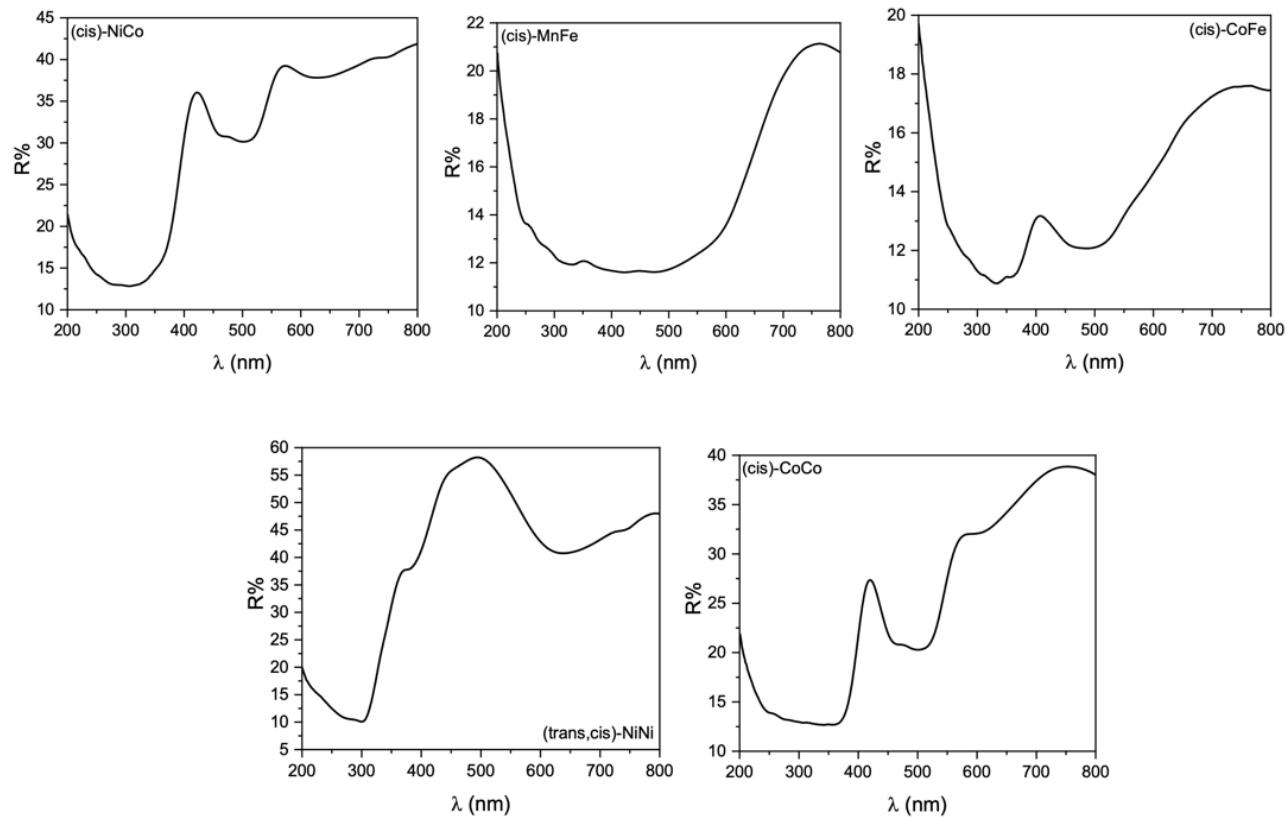

**Figure S10.** SEM images of a) NTC matrix + **(trans,cis)-NiFe** untreated; b) NTC matrix + **(trans,cis)-NiFe** treated with KOH; c) NTC matrix + **(trans,cis)-NiFe** treated with KOH after 1CV; NTC matrix + **(trans,cis)-NiFe** treated with KOH after 50 CVs.

**Table S3.** Observed Ni:Fe and M:O ratio based on EDX analysis.

Sample	Ni : Fe
<b>(trans,cis)-NiFe</b>	1 : 0.7
<b>NTC matrix + (trans,cis)-NiFe untreated</b>	1 : 0.4
<b>NTC matrix + (trans,cis)-NiFe 1M KOH 30s</b>	1 : 0.7
<b>NTC matrix + (trans,cis)-NiFe 1M KOH 30s 1CV</b>	1 : 0.4
<b>NTC matrix + (trans,cis)-NiFe 1M KOH 30s 50CV</b>	1 : 0.5

## S8 Reflectance spectra

Diffuse reflectance recorded from the powder samples display different contributions from scattering process (evaluated from R% at 800 nm), which are likely due to different grain size of the samples.

**Figure S11.** Reflectance spectra of the investigated samples.

## **II. Computational Part**

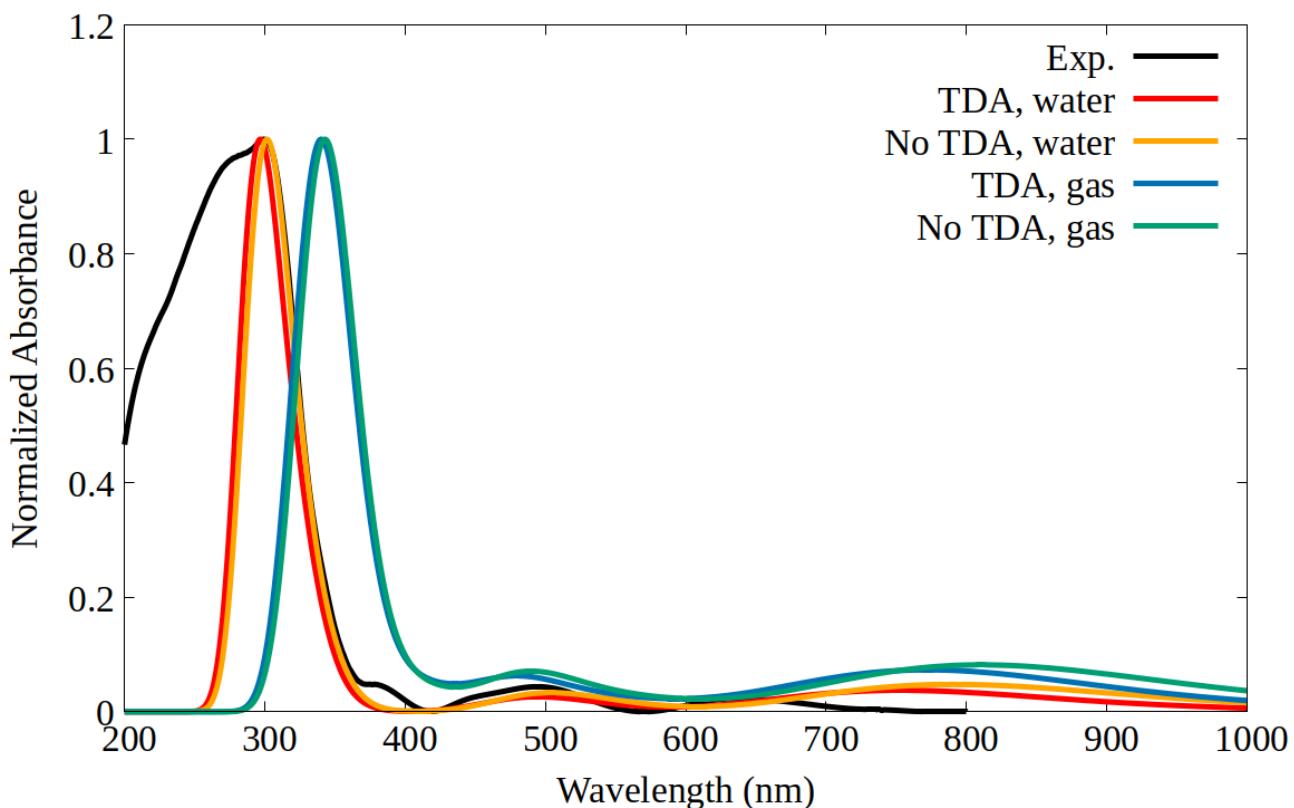

### **S9 Computational protocol**

All calculations were carried out using the ORCA quantum chemistry program package based v. 5.0.3.<sup>6</sup> Geometry optimizations were carried out using the B3LYP functional together with Grimme's D3 dispersion correction and Becke-Johnson damping.<sup>7-12</sup> The Ahlrichs def2-TZVP(-f) basis set was used for all the calculations, unless otherwise specified.<sup>13</sup> To model CPs, we defined a molecular cluster with two metal centers fully coordinated by water and oxonato ligands, in which the environment, i.e., the remaining of the system and (if present) the water solvent, is treated using an implicit solvation approach (C-PCM).<sup>14,15</sup> The dielectric constant of water was used as a model. This computational protocol is denoted hereafter as B3LYP-D3+C-PCM(Water)/def2-TZVP(-f). Excited states were calculated at the same level of theory within the TDDFT framework. Unless otherwise specified, the Tamm-Danoff Approximation (TDA) was used in all TDDFT calculations. The default SCF convergence criteria and DFT grid settings (defgrid2) of ORCA v. 5.0.3 were used in all cases. For the Raman spectra the polarizability was computed analytically by solving the CP-SCF equations (POLAR 1). When two deprotonated water molecules bind to Fe, constraints were employed for the metals and the atoms with dangling bonds. In this case Partial Hessian Vibrational Analysis (PHVA) calculations were run.<sup>16</sup>

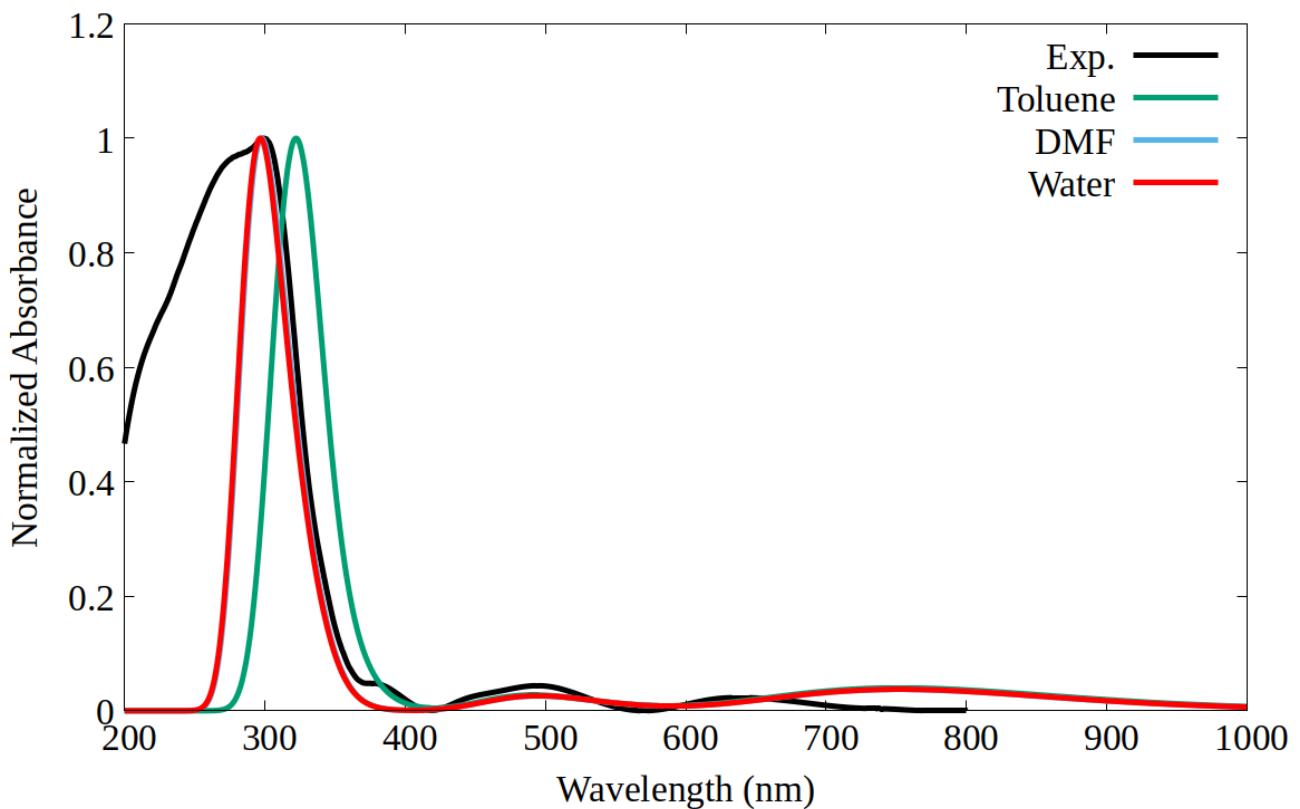

## S10 Method and model validation

In this section we calibrate our computational protocol by comparing the experimental absorption spectra in the solid phase with the computed spectra on our model systems using various computational settings.

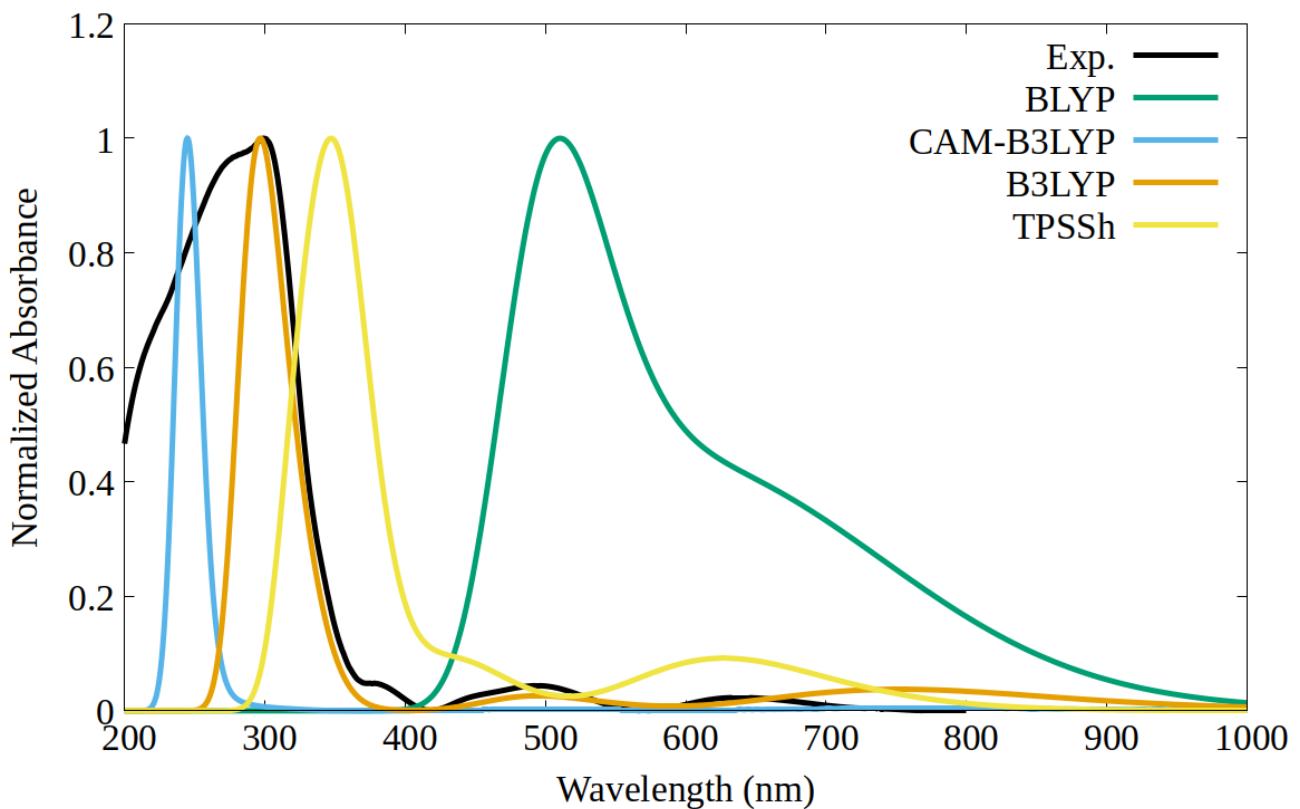

**Figure S12****Figure S15** show the spectra obtained for **(trans,cis)-NiNi**.

**Figure S12.** Experimental and computed UV/VIS spectra for **(trans,cis)-NiNi**. The model features an overall spin multiplicity of 5. The computed spectra were obtained with various computational settings for the environment and with and without the TDA approximation. The agreement between theory and experiment improves when an implicit solvation model is used. In addition, the TDA approximation has essentially no effect on the spectra.

**Figure S13.** Computed vs experimental UV/VIS spectra for **(trans,cis)-NiNi** considering Toluene, DMF and water within the C-PCM model. While there is not noticeable difference between the spectra computed with water and DMF, which show a remarkable agreement between theory and experiment for both systems, a significant red shift in the maxima is observed with toluene. This is consistent with its significantly smaller dielectric constant.

**Figure S14.** Computed vs experimental UV/VIS spectra for **(trans,cis)-NiNi** using different exchange-correlation functionals (BLYP, B3LYP, CAM-B3LYP and TPSSh). The hybrid B3LYP functional shows the best agreement between theory and experiment.

## S11 Ground state electronic structure

**Table S4-Table S14** show the energy difference ( $\Delta E$ ) between the electronic spin states of the CPs investigated in this work for various conformers and coordination environments, together with the corresponding Mulliken spin populations (**SP**) at the metal centers. The results show how each metal prefers a high spin configuration in the lowest energy ground state, regardless of its coordination environment.

**Table S4.** Electronic energy differences ( $\Delta E$ ), Mulliken spin populations (**SP**) and total spin multiplicity ( $S_{\text{tot}}$ ) for the various electronic spin states of **(trans,cis)-NiNi**.

$S_{\text{tot}}$	$\Delta E$ (eV)	SP Ni(trans)	SP Ni(cis)
<b>1</b>	1.79	-	-
<b>3</b>	0.64	0.0	1.7
<b>5</b>	0	1.7	1.7

**Table S5.** Electronic energy differences ( $\Delta E$ ), Mulliken spin populations (**SP**) and total spin multiplicity ( $S_{\text{tot}}$ ) for the various electronic spin states of **(cis)-CoCo**. Both metal centers show the **cis** coordination environment.

## S12 Validation of the ground state spin configuration

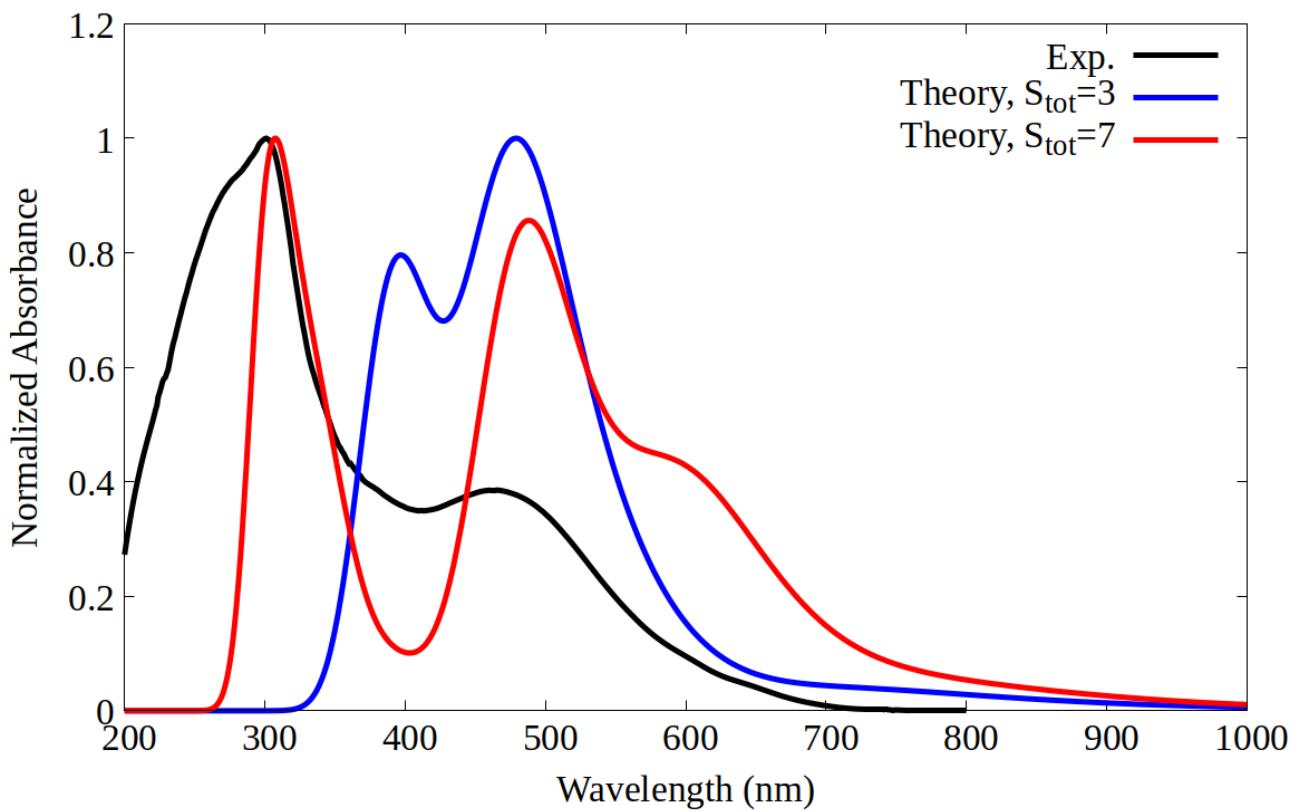

In **Figure S15****Figure S18** the experimental (black) and the computed absorption spectra for **(trans,cis)-NiNi**, **(trans,cis)-NiCo**, **(trans,cis)-NiFe** and **(cis)-MnFe** with different total spin multiplicities ( $S_{\text{tot}}$ ) are shown. The best agreement between experimental end computed spectra is obtained when considering each metal center in its highest spin configuration. This is consistent with the thermodynamic evaluation of the energy difference between the electronic spin states, demonstrating that the ground state features both metal centers in their high-spin configuration. The computed spectra for the bimetallic CPs are the convolution of the spectra obtained for both coordination environment combinations, i.e., the M1(trans)M2(cis) and M1(trans)M2(cis) clusters. This was done in order to consider the dependency of the optical properties on the coordination environment for the two metal centers in the bimetallic case.

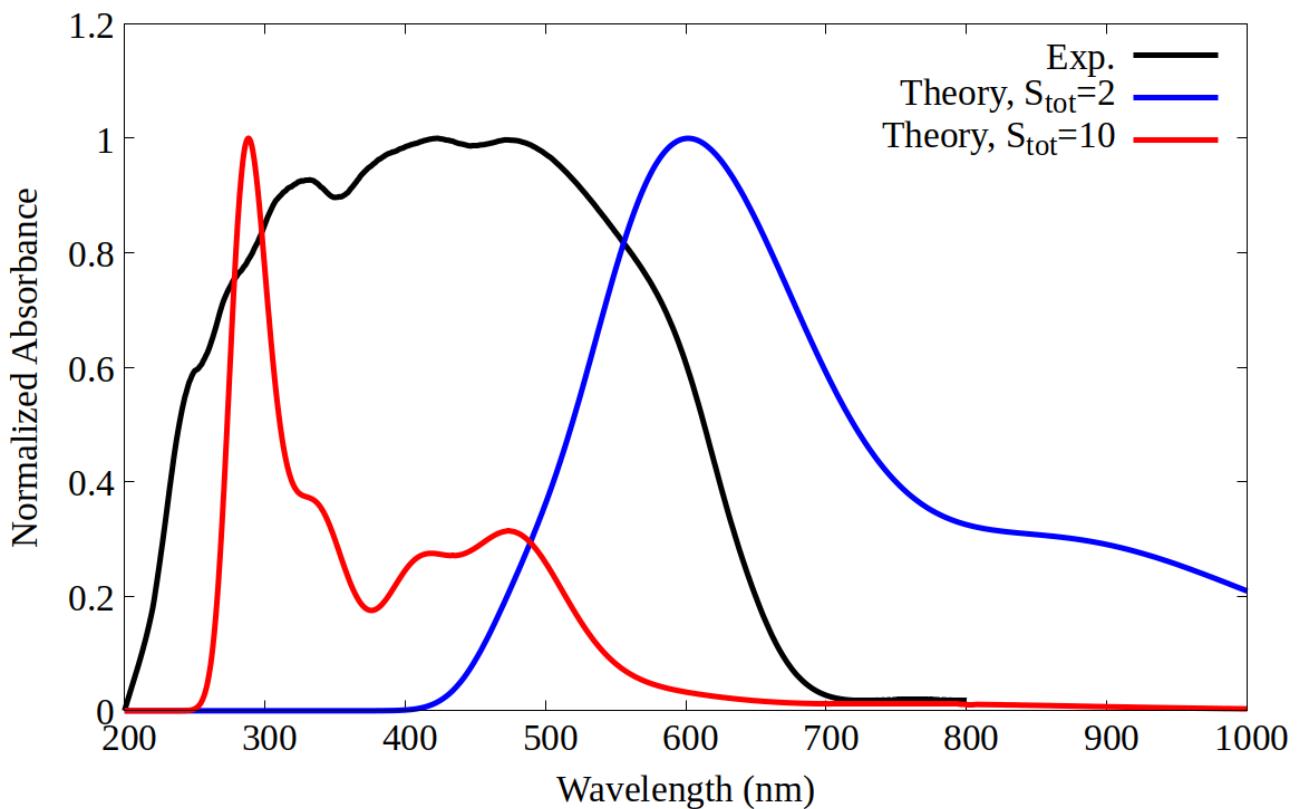

**Figure S15.** Comparison of the experimental and theoretical spectra for **(trans,cis)-NiNi** with total  $S_{\text{tot}}$  equal to 3 and 5.

**Figure S16.** Comparison of the experimental and theoretical spectra for (**trans,cis**)-NiCo with  $S_{\text{tot}}$  equal to 4 and 6.

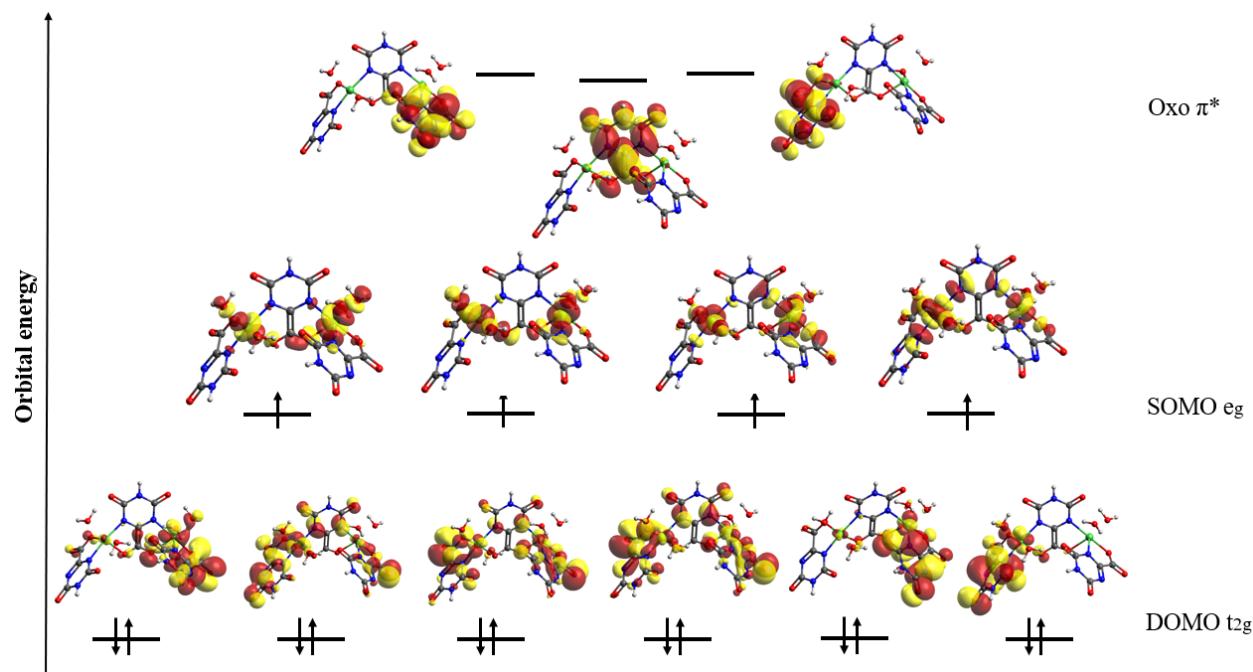

**Figure S17.** Comparison of the experimental and theoretical spectra for **(trans,cis)-NiFe** with total  $S_{\text{tot}}$  equal to 3 and 7.

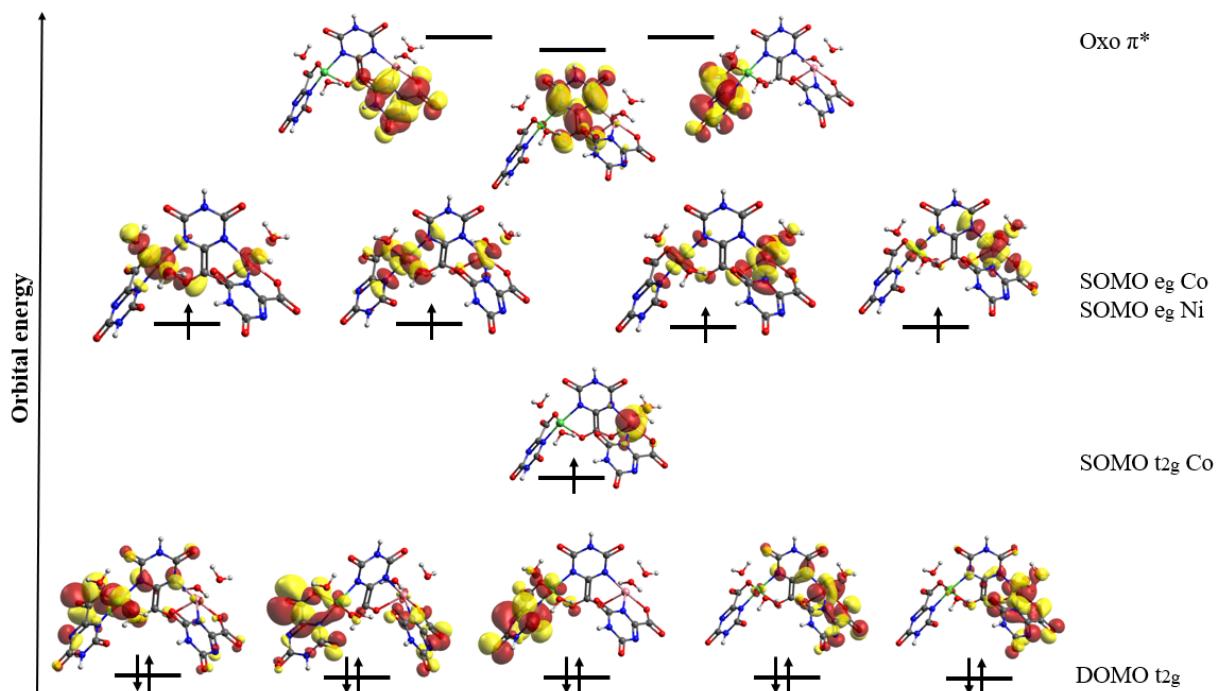

**Figure S18.** Comparison of the experimental and theoretical spectra for **(cis)-MnFe** with total  $S_{\text{tot}}$  equal to 2 and 10.

### S13 Electronic structure characterization

To provide a visual representation of the ground state electronic structure of the systems considered in this work, we provide a qualitative orbital energy diagram for prototypical examples using quasi-restricted orbitals (QROs).

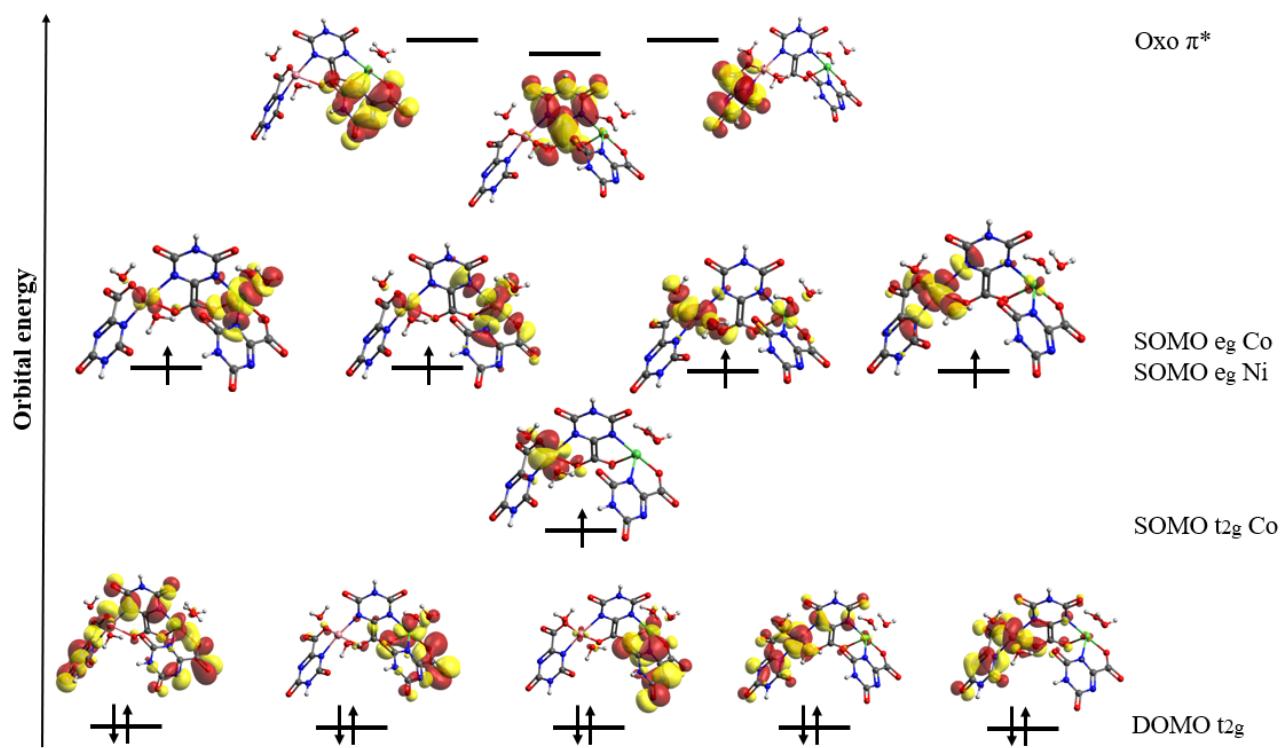

**Figure S19.** Electronic structure of (trans,cis)-NiNi for  $S_{\text{tot}}$  equal to 5.

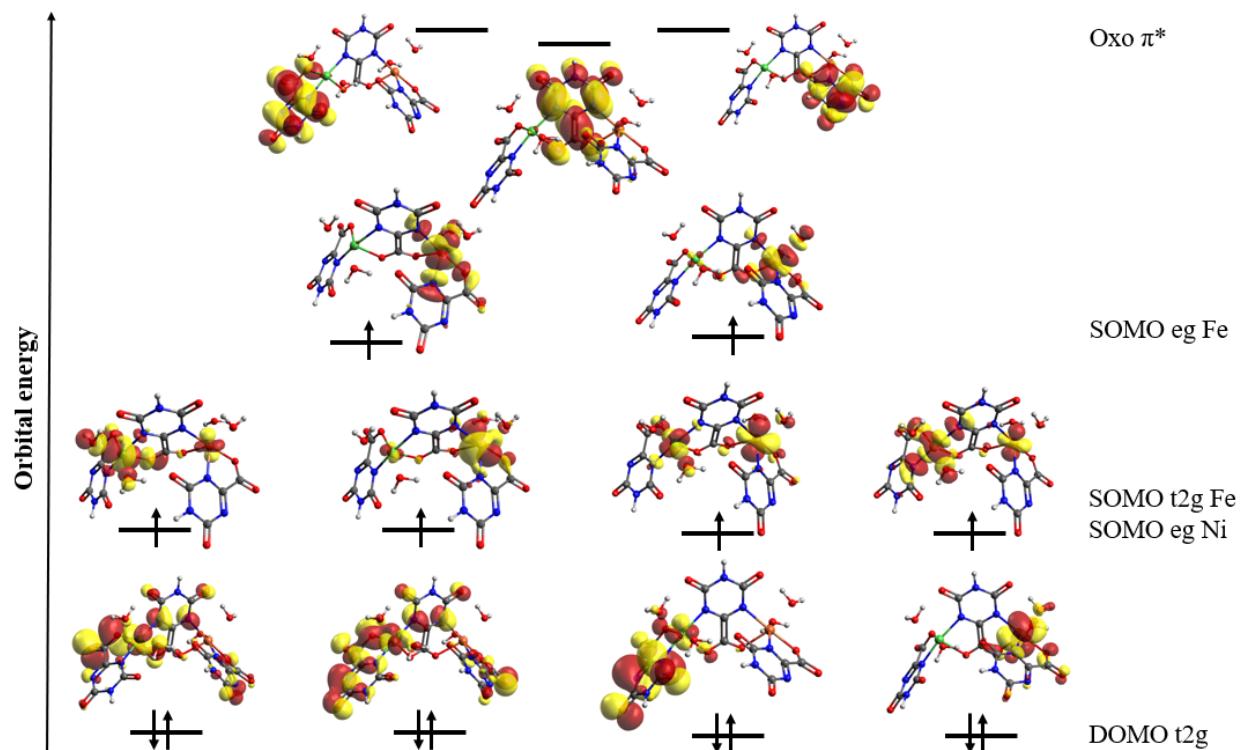

**Figure S20.** Electronic structure of (trans,cis)-NiCo for  $S_{\text{tot}}$  equal to 6, with Co (pink) and Ni (green) in

**cis** and **trans** coordination environments respectively.

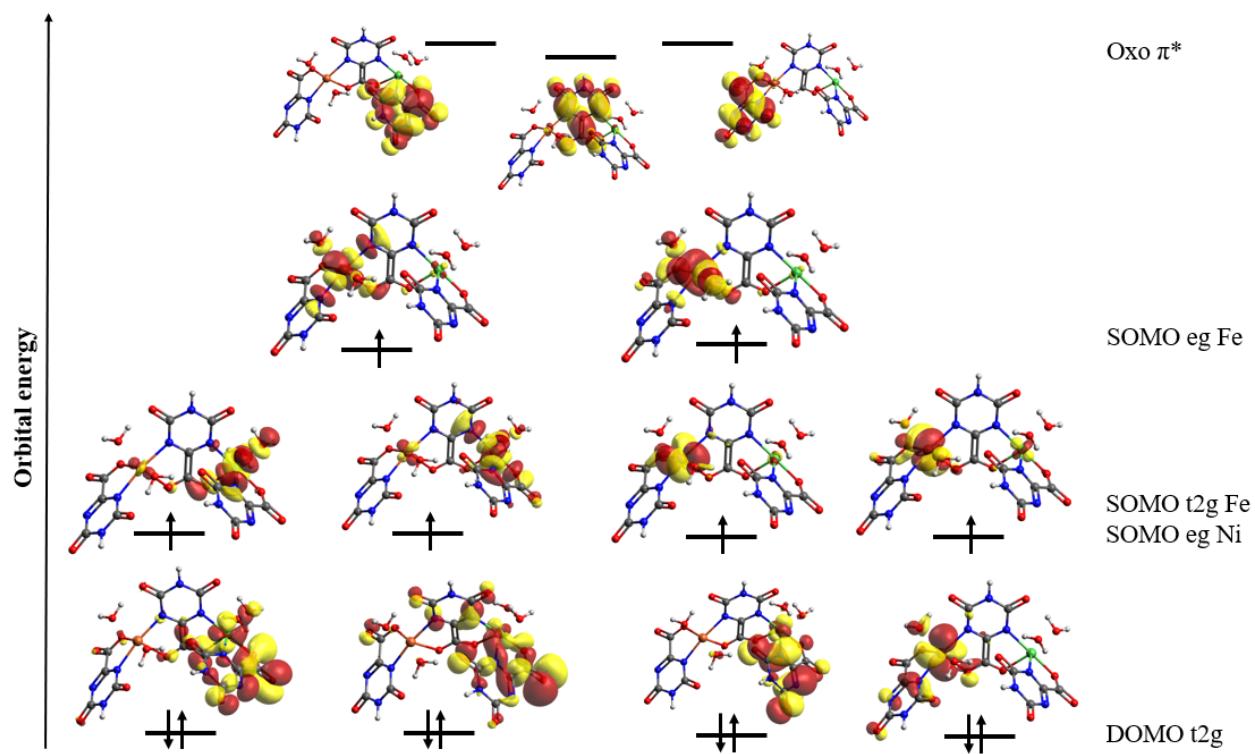

**Figure S21.** Electronic structure of **(trans,cis)-NiCo** for  $S_{\text{tot}}$  equal to 6, with Ni (green) and Co (pink) in **cis** and **trans** coordination environments respectively.

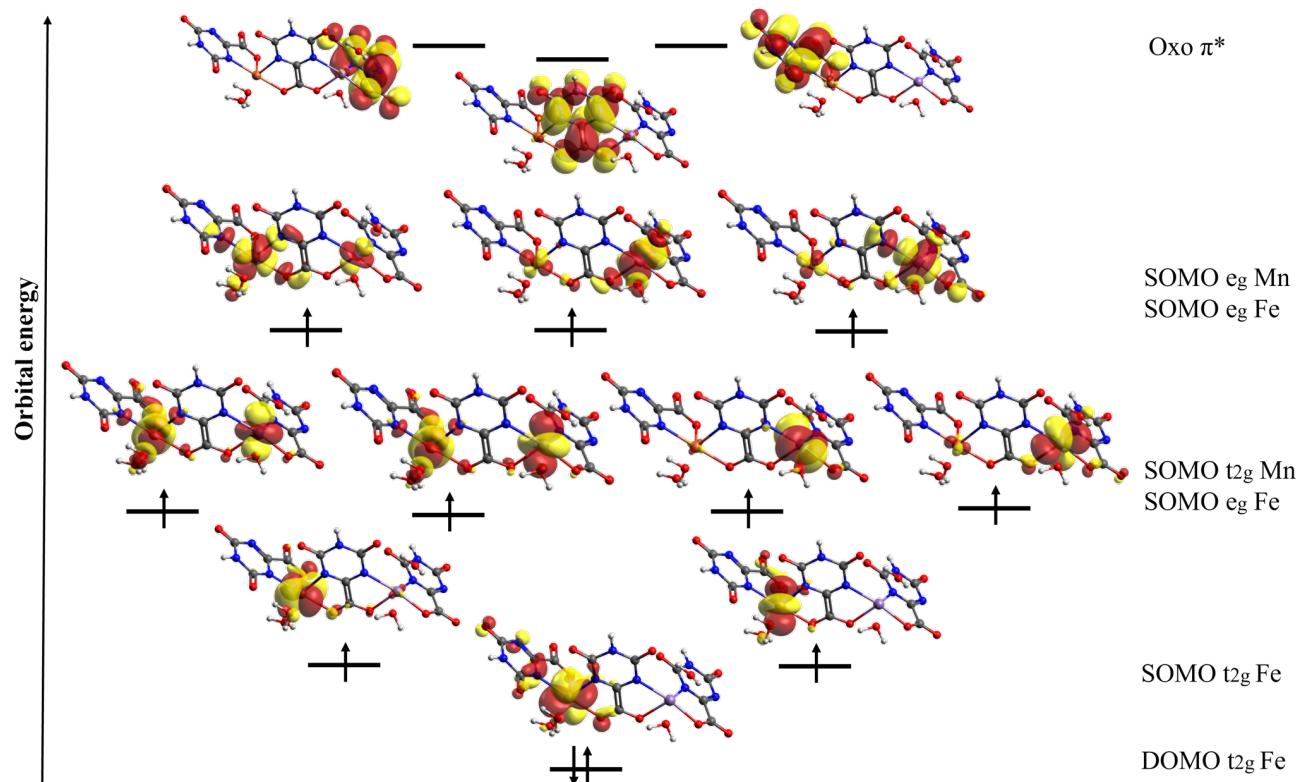

**Figure S22.** Electronic structure of **(trans,cis)-NiFe** for  $S_{\text{tot}}$  equal to 7, with Fe (orange) and Ni (green)

in **cis** and **trans** coordination environments respectively.

**Figure S23.** Electronic structure of **(trans,cis)-NiFe** for  $S_{\text{tot}}$  equal to 6, with Ni (green) and Fe (orange) in **cis** and **trans** coordination environments respectively.

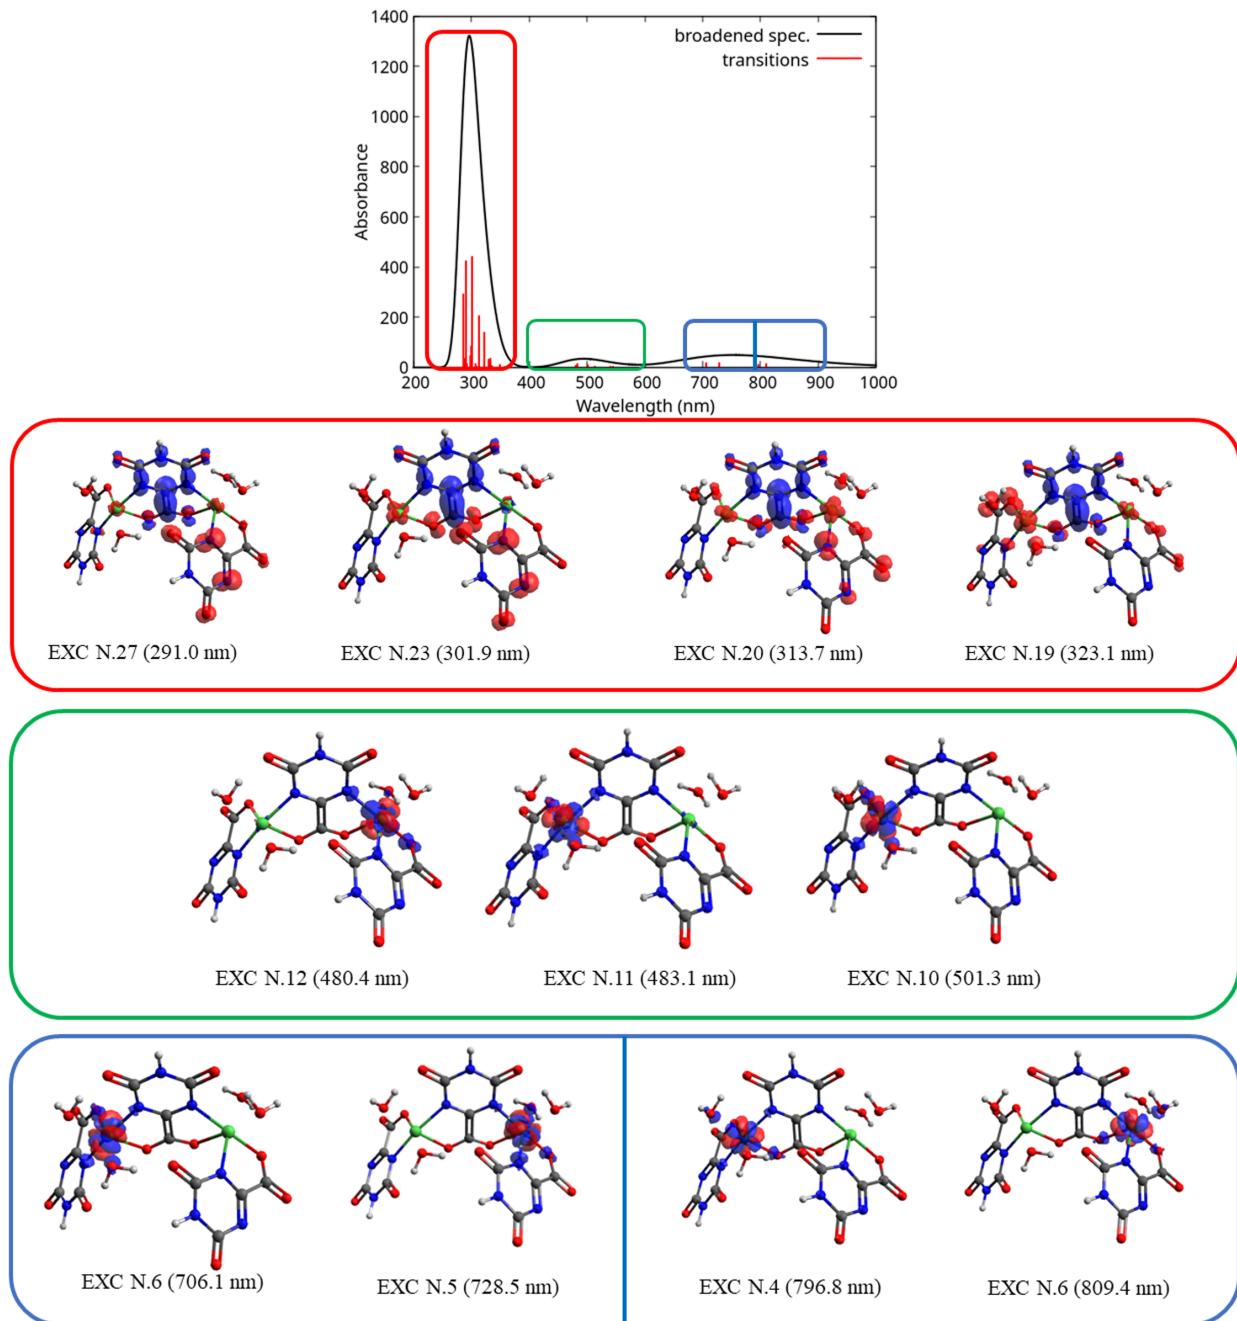

**Figure S24.** Electronic structure of **(cis)-MnFe** for  $S_{\text{tot}}$  equal to 10, with both Fe (orange) and Mn (purple)

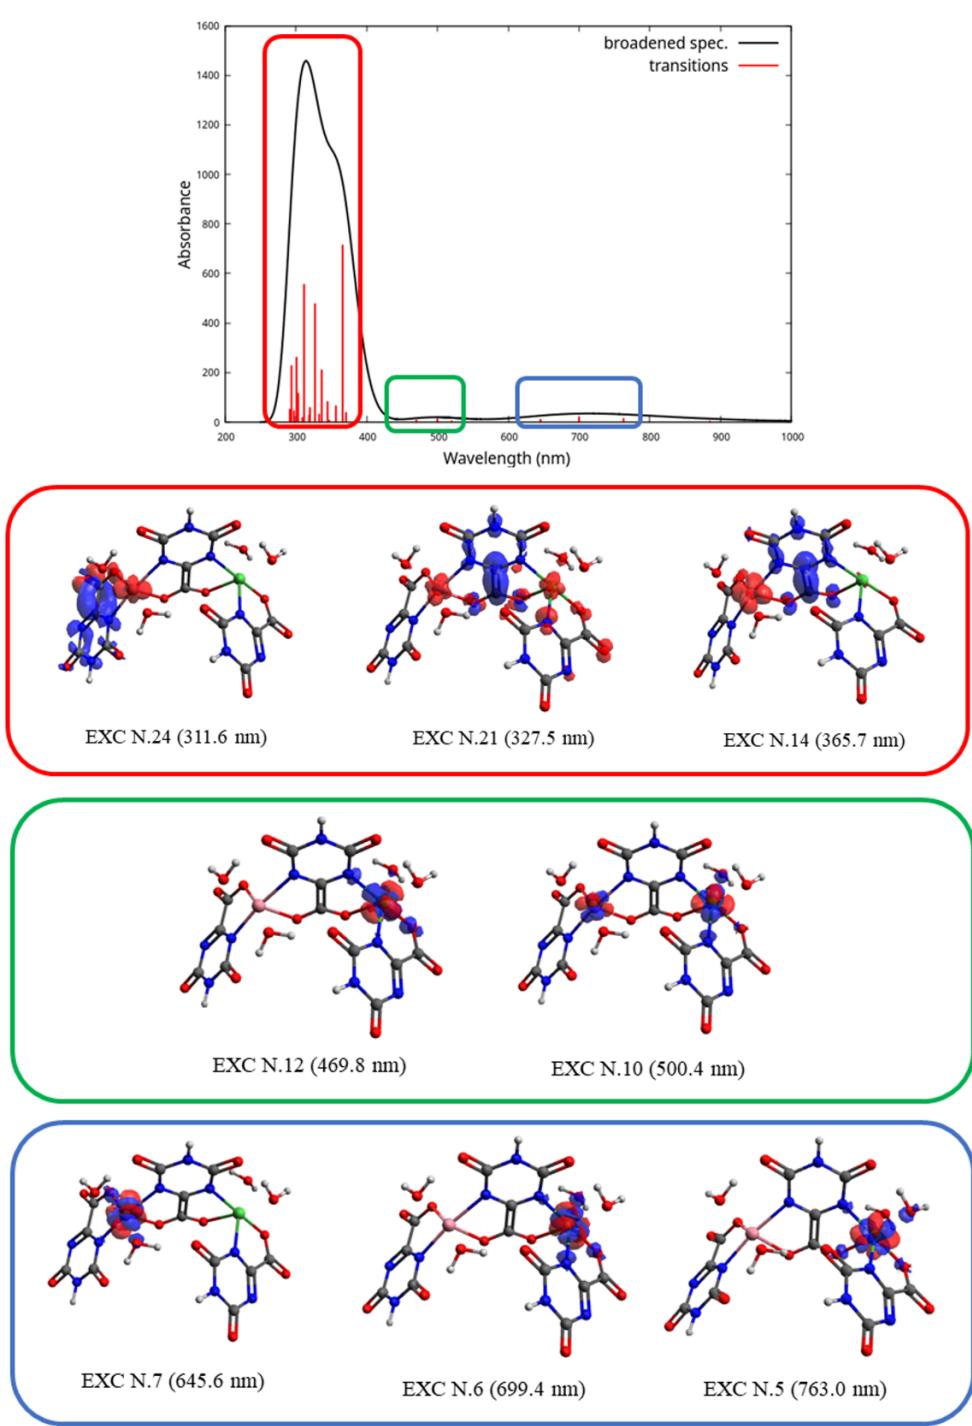

S32

in **cis** coordination environment.

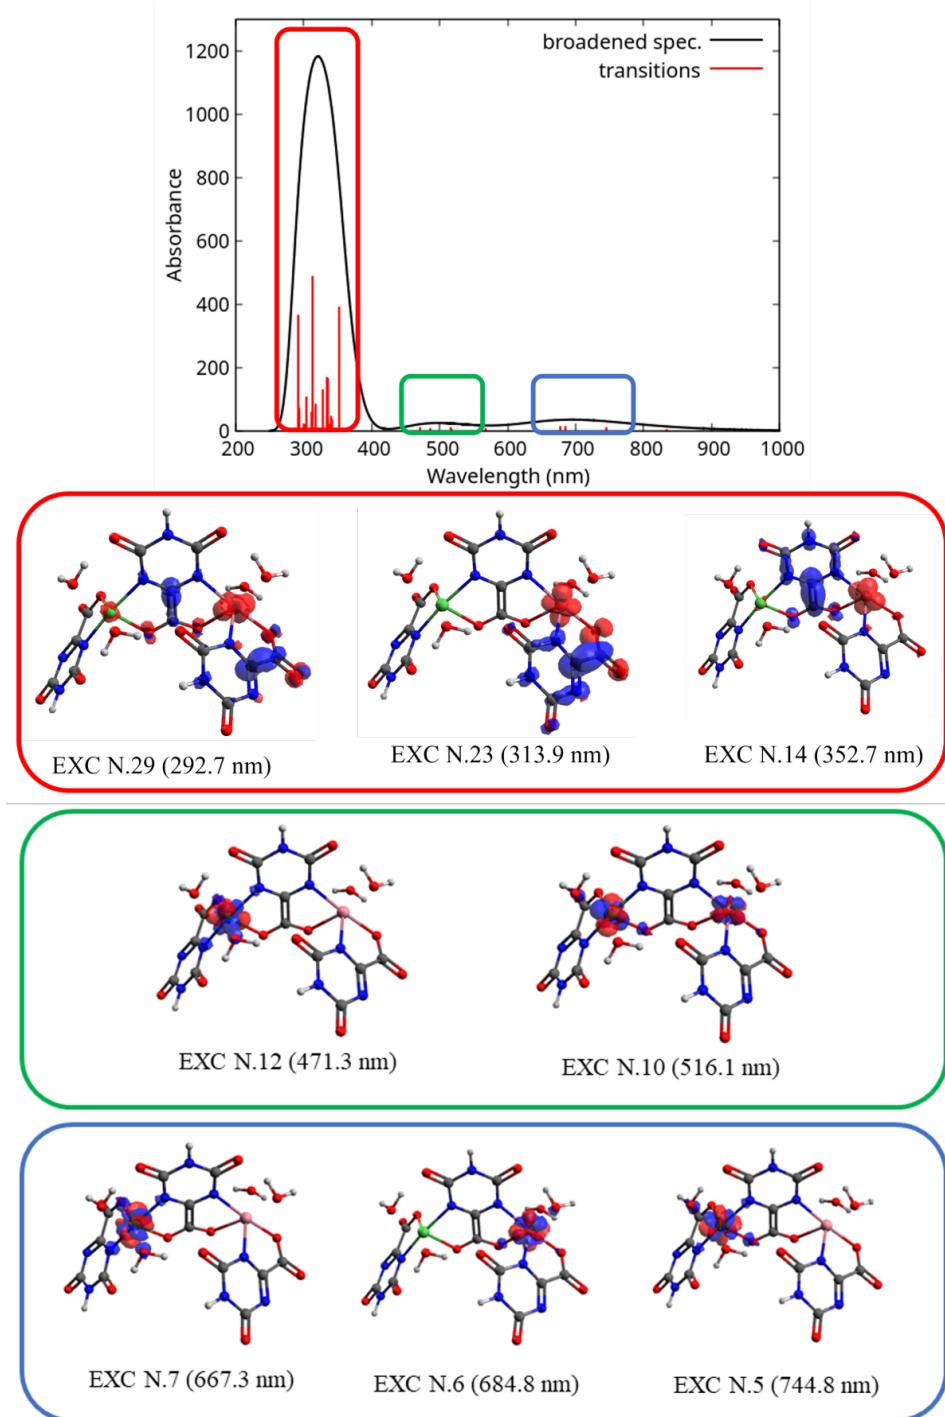

## S14 Electronic transitions characterization

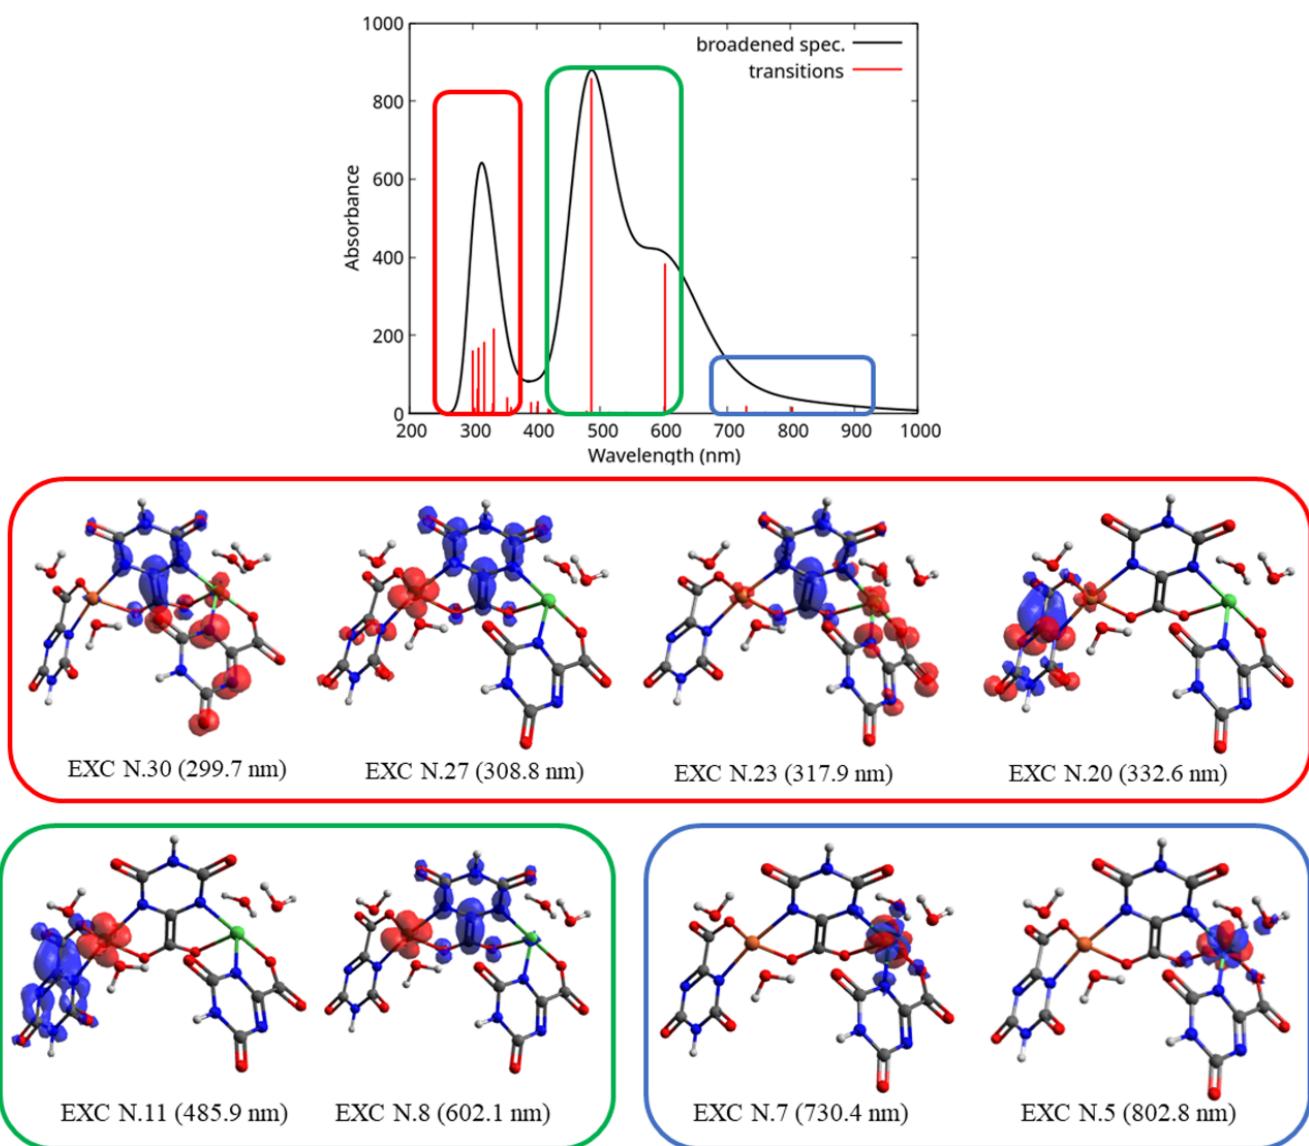

**Figure S25.** Characterization of the electronic excitations using difference densities for **(trans,cis)-NiNi** with  $S_{\text{tot}}$  equal to 5. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

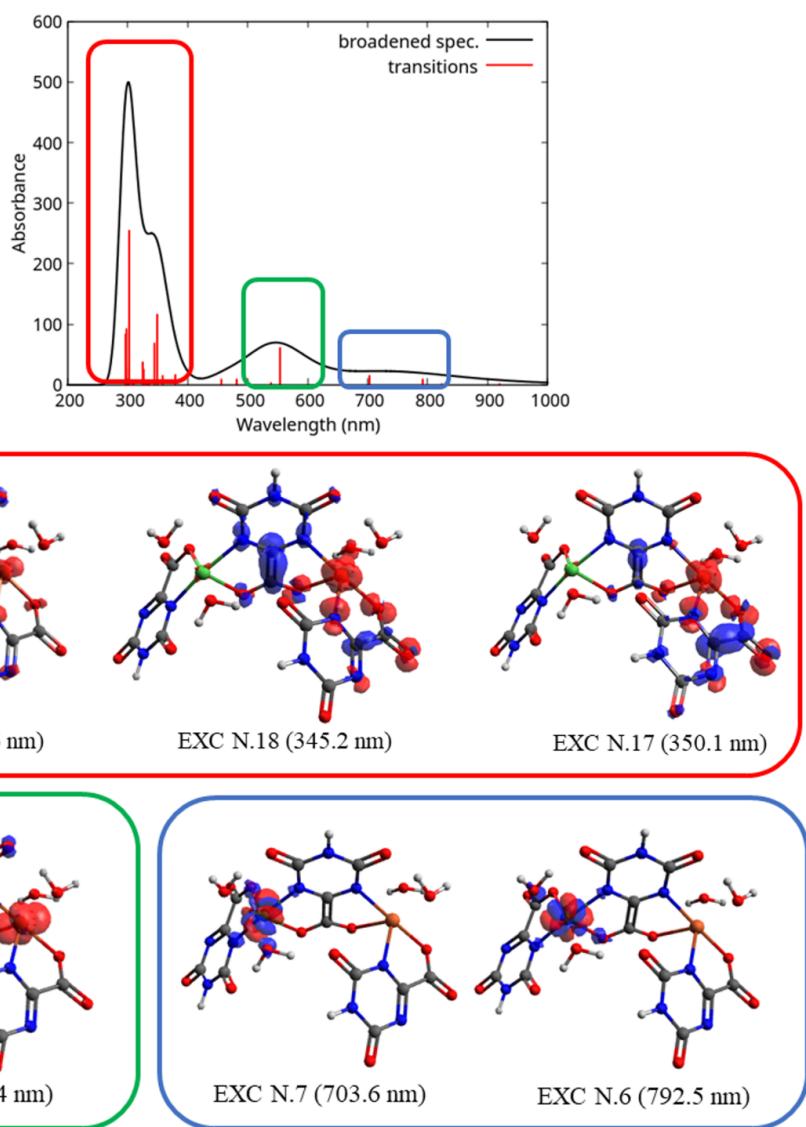

**Figure S26.** Characterization of the electronic excitations using difference densities for **(trans,cis)-NiCo**, where Ni (green) and Co (pink) are in **cis** and **trans** coordination environments respectively, and  $S_{\text{tot}}$  equal to 6. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

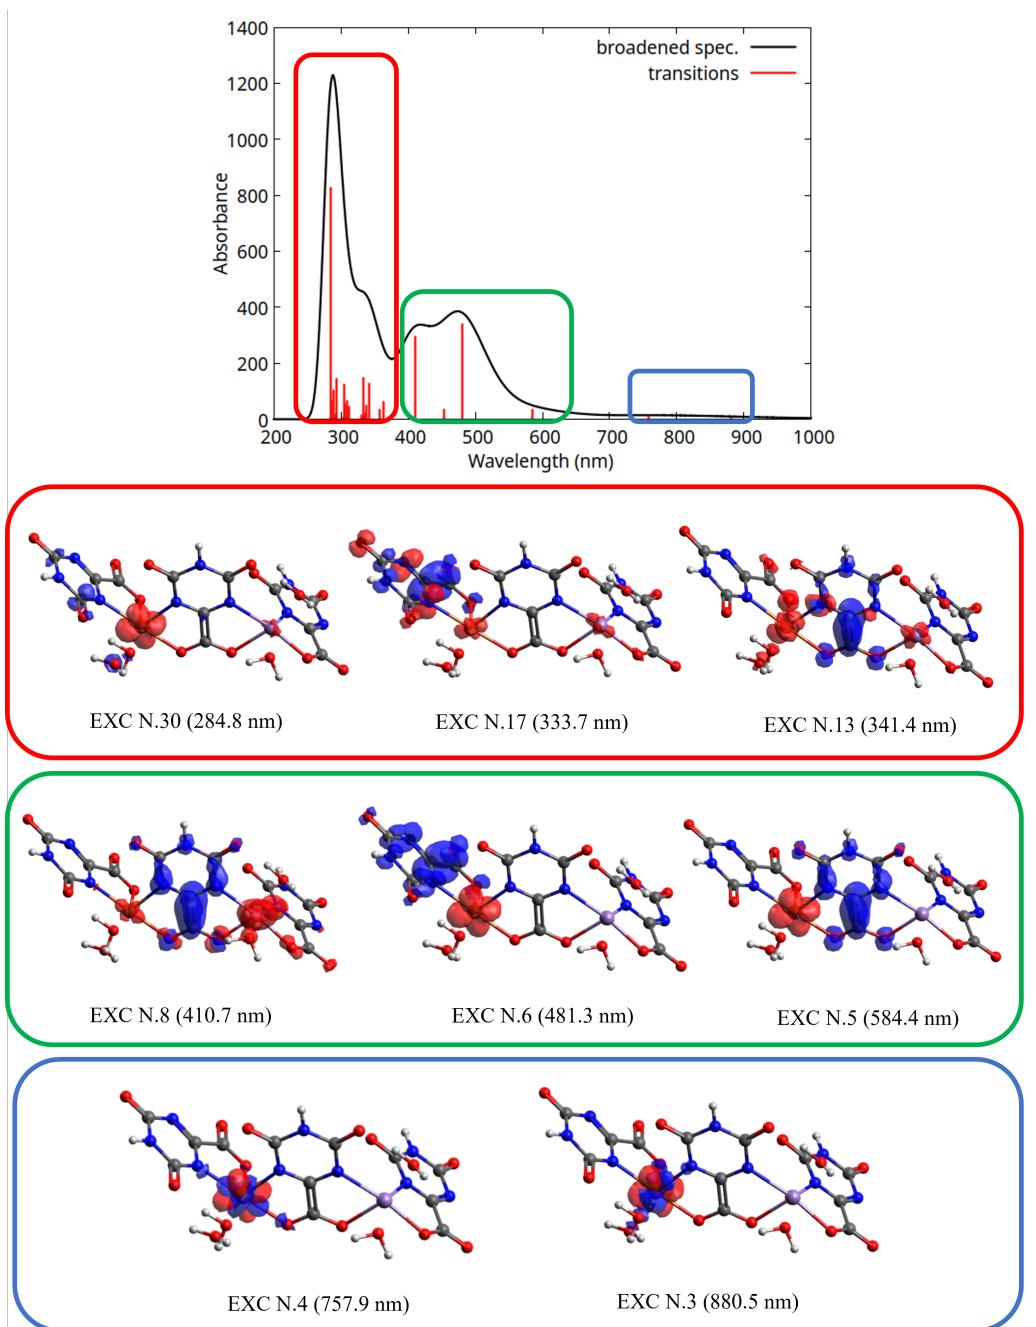

**Figure S27.** Characterization of the electronic excitations using difference densities for **(trans,cis)-NiCo**, where Ni (green) and Co (pink) are in **trans** and **cis** coordination environments respectively, and  $S_{tot}$  equal to 6. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

**Figure S28.** Characterization of the electronic excitations using difference densities for **(trans,cis)-NiFe**, where Ni (green) and Fe (orange) are in **cis** and **trans** coordination environments respectively, and  $S_{tot}$  equal to 7. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

**Figure S29.** Characterization of the electronic excitations using difference densities for **(trans,cis)-NiFe**, where Ni (green) and Fe (orange) are in **trans** and **cis** coordination environments respectively, and  $S_{tot}$  equal to 7. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

**Figure S30.** Characterization of the electronic excitations using difference densities for **(cis)-MnFe**, where both Mn (violet) and Fe (orange) are in **cis** coordination environments, and  $S_{\text{tot}}$  equal to 10. Red surfaces correspond to regions of charge depletion, while blue surfaces correspond to regions of charge accumulation.

## S15 OER reaction free energies in alkaline conditions

To obtain the free energy diagrams for the catalysts considered in this work, it is necessary to derive the reaction energies for each elementary step under alkaline conditions:<sup>17-19</sup>

In which M is the catalyst (in the present example, the catalyst features an uncoordinated site that can be occupied by the incoming OH).  $\Delta G_i$  is defined as the difference of the electrochemical potentials of products and reagents for all the four steps:

$$\Delta G_1 = \mu_{OH^*} - \mu_{i*} - (\mu_{OH^-} - \mu_{e^-}) \quad \text{Eq. S5}$$

$$\Delta G_2 = \mu_{O^*} + \mu_{H_2O} - \mu_{OH^*} - (\mu_{OH^-} - \mu_{e^-}) \quad \text{Eq. S6}$$

$$\Delta G_3 = \mu_{OOH^*} - \mu_{O^*} - (\mu_{OH^-} - \mu_{e^-}) \quad \text{Eq. S7}$$

$$\Delta G_4 = \mu_{i*} + \mu_{O_2} + \mu_{H_2O} - \mu_{OOH^*} - (\mu_{OH^-} - \mu_{e^-}) \quad \text{Eq. S8}$$

Where  $\mu$  are the electrochemical potentials of the species involved in the steps (\* denotes the intermediate with a specific species absorbed on the metal).

The  $O_2$  potential is derived from the experimental standard free energy formation of the reaction  $\frac{1}{2}O_{2(g)} + H_{2(g)} \leftrightarrow H_{2(l)}$ , which amounts to 2.46eV. It follows that the  $O_2$  potential is equal to:

$$\mu_{O_{2(g)}} = 4.92 + 2\mu_{H_{2(l)}} - 2\mu_{H_{2(g)}} \quad \text{Eq. S9}$$

To obtain  $OH^-$  and  $e^-$  potentials (only their difference is needed, see Eq. S5 Eq. S8), we assume the equilibrium:

The related potentials will be:

$$\mu_{H_2O} = \mu_{H^+} + \mu_{OH^-} \quad \text{Eq. S11}$$

Adding to both sides the same term  $\mu_{e^-}$  we obtain:

$$\mu_{\text{OH}^-} - \mu_{\text{e}^-} = \mu_{\text{H}_2\text{O}} - (\mu_{\text{H}^+} + \mu_{\text{e}^-}) \quad \text{Eq. S12}$$

The  $(\mu_{\text{H}^+} + \mu_{\text{e}^-})$  term can be calculated using the computational hydrogen electrode (CHE) approach,<sup>20</sup> assuming the equilibrium:

The final OER energy profiles are expressed using the reversible hydrogen electrode (RHE) as reference:

$$\Delta G_1 = \mu_{\text{OH}^*} - \mu_i - \mu_{\text{H}_2\text{O}} + \frac{1}{2}\mu_{\text{H}_2} - eU_{\text{RHE}} \quad \text{Eq. S14}$$

$$\Delta G_2 = \mu_{\text{O}^*} - \mu_{\text{OH}^*} + \frac{1}{2}\mu_{\text{H}_2} - eU_{\text{RHE}} \quad \text{Eq. S15}$$

$$\Delta G_3 = \mu_{\text{OOH}^*} - \mu_{\text{O}^*} - \mu_{\text{H}_2\text{O}} + \frac{1}{2}\mu_{\text{H}_2} - eU_{\text{RHE}} \quad \text{Eq. S16}$$

$$\Delta G_4 = \mu_{\text{i}^*} - \mu_{\text{OOH}^*} + \mu_{\text{O}_2} + \frac{1}{2}\mu_{\text{H}_2} - eU_{\text{RHE}} \quad \text{Eq. S17}$$

In the CPs under study, two water molecules are already coordinated to each metal center, and hence each node presents two active sites. Unless otherwise specified, we will assume that the reaction occurs on a single active site, while keeping all the remaining positions coordinated with water. Notably, the dissociation energy of a single water molecule under the experimental conditions is close to 0 eV.

## S16 Reaction intermediates analysis

**Table S15.** Intermediates reaction free energies ( $\Delta G$ ), total spin multiplicity ( $S_{\text{tot}}$ ), Mulliken spin populations (SP) for the neighbor metal **M**, the active site **M** and the evolving oxygen **O**, the **M-O** distance ( $d_{\text{M-O}}$ , in Å) and the Mayer bond order (BO) related to the product of each step for (**trans,cis**)-**NiNi**.
