## Experimental section

### Catalysts

The catalysts were synthesized using wet impregnation technique, whose procedures depicted in our previous studies<sup>1-4</sup> were slightly modified. In the case of TiO<sub>2</sub>-supported Ni<sub>1</sub>V<sub>2</sub>O<sub>6</sub> (Ni<sub>1</sub>), Ni<sub>2</sub>V<sub>2</sub>O<sub>7</sub> (Ni<sub>2</sub>), or Ni<sub>3</sub>V<sub>2</sub>O<sub>8</sub> (Ni<sub>3</sub>) catalyst, 'A' g of TiO<sub>2</sub> (DT51, CristalACTIV™) was mixed with 170 mL of de-ionized H<sub>2</sub>O and stirred at 25 °C for half an hour before being further mixed with 2.36 mmol of NH<sub>4</sub>VO<sub>3</sub> (≥ 99.0 %, Junsei) and 2.36 mmol of (COOH)<sub>2</sub>·2H<sub>2</sub>O (oxalic acid, 99.5-100 %, Junsei), both of which were dissolved in 70 mL of de-ionized H<sub>2</sub>O (A of 5.81 g for Ni<sub>1</sub>; 5.74 g for Ni<sub>2</sub>; 5.67 g for Ni<sub>3</sub>). The resulting mixture was then stirred at 25 °C for half an hour, mixed with 'B' mmol of Ni(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O (≥ 97.0 %, Junsei) dissolved in 70 mL of de-ionized H<sub>2</sub>O, stirred at 25 °C for 18 hours, subjected to rotary evaporation for the removal of de-ionized H<sub>2</sub>O, dried at 110 °C for 18 hours, and calcined at 500 °C for 5 hours with a ramping rate of 5 °C min<sup>-1</sup> (B of 1.18 mmol for Ni<sub>1</sub>; 2.36 mmol for Ni<sub>2</sub>; 3.54 mmol for Ni<sub>3</sub>). Meanwhile, 12.3 mmol of Sb(CH<sub>3</sub>COO)<sub>3</sub> (≥ 97.0 %, Alfa Aesar) was dissolved in 500 mL of CH<sub>3</sub>COOH (acetic acid, 99.5-100.5 %, J. T. Baker), stirred at 25 °C for half an hour, mixed with 48.5 g of TiO<sub>2</sub>, stirred at 25 °C for 18 hours, subjected to rotary evaporation for the removal of acetic acid, dried at 110 °C for 18 hours, and calcined at 500 °C for 5 hours with a ramping rate of 5 °C min<sup>-1</sup> for the production of antimony oxide supported on TiO<sub>2</sub> (Sb/TiO<sub>2</sub>).<sup>1-4</sup> Sb-promoted Ni<sub>1</sub> catalyst (Ni<sub>1</sub>-Sb) was then synthesized according to the protocols identical to those utilized to synthesize Ni<sub>1</sub> except for the use of Sb/TiO<sub>2</sub> as a support. WO<sub>3</sub>-promoted V<sub>2</sub>O<sub>5</sub> supported on TiO<sub>2</sub> (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>) was synthesized according to the protocols we reported elsewhere<sup>1, 2, 4</sup> and served to simulate a commercial catalyst. The catalyst finally underwent surface modification with SO<sub>4</sub><sup>2-</sup>/HSO<sub>4</sub><sup>-</sup> (Z= 3-4) functionalities, for which the catalyst was exposed to 500 ppm SO<sub>2</sub>/3 vol. % O<sub>2</sub>/N<sub>2</sub> at 500 °C for an hour with a total flow rate of 500 mL min<sup>-1</sup> and a ramping rate of 10 °C min<sup>-1</sup>.<sup>1-6</sup> This led to the generation of SO<sub>4</sub><sup>2-</sup>/HSO<sub>4</sub><sup>-</sup>-modified Ni<sub>1</sub> (Ni<sub>1</sub>-S), Ni<sub>2</sub> (Ni<sub>2</sub>-S), Ni<sub>3</sub> (Ni<sub>3</sub>-S), Ni<sub>1</sub>-Sb (Ni<sub>1</sub>-Sb-S), or V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub> (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S).

### Characterizations

X-ray diffraction (XRD) patterns of the catalysts were acquired on a D8 Advance diffractometer (Bruker) with the analytic conditions of 20-80° for 2θ range, 0.02° per step for step size, 2 seconds per step for scan speed in addition to the use of Cu K<sub>α</sub> radiation with the wavenumber of 0.154 nm. X-ray fluorescence (XRF) analysis of the catalysts were performed on a ZSX Primus II spectrometer (Rigaku). High-resolution transmission electron microscopy (HRTEM) images and selected area electron diffraction (SAED) patterns of the catalysts were acquired on a Titan 80-300™ (FEI) with the acceleration voltage of 300 keV after the catalyst surfaces were purged under vacuum (~10<sup>-7</sup> mmHg). Energy-dispersive X-ray spectroscopy (EDX) mapping images of the catalysts were acquired using an Ultim max 170 (Oxford) at 15 kV after the catalyst surfaces were purged under vacuum (~10<sup>-6</sup> mmHg). X-ray photoelectron spectroscopy (XPS) spectra of the catalysts were acquired with the resolution of 0.05 eV on a PHI 5000 VersaProbe after the catalyst surfaces were purged under vacuum (~10<sup>-4</sup> mmHg). XPS spectra of the catalysts were curve-fitted using Gaussian function, with which adventitious carbon band situated at binding energy centered at ~284.6 eV was used as a reference to correct binding energies of XPS spectra in the Ni 2p, V 2p, S 2p, and O 1s regimes. (See Table S2.) Temperature-resolved Raman spectra of the catalysts were acquired under a N<sub>2</sub> at 25 °C or 220 °C with the resolution of 0.3 cm<sup>-1</sup> on an inVia Raman Microscope (Renishaw) coupled with X 50 objective lens and a 532 nm excitation laser after the catalyst surfaces were purged with a N<sub>2</sub> at 300 °C for half an hour with a total flow rate of 300 mL min<sup>-1</sup> and a ramping rate of 10 °C min<sup>-1</sup>.<sup>3</sup> Raman spectra of the catalysts were curve-fitted using Gaussian function.<sup>3</sup> N<sub>2</sub> isotherms of the catalysts were acquired on a NOVA 2200e (Quantachrome Instruments) at -196 °C after the catalyst surfaces were purged under vacuum (2 X 10<sup>-3</sup> mmHg). Brunauer-Emmett-Teller (BET) and Barrett-Joyner-Halenda (BJH) theories were utilized to evaluate N<sub>2</sub>-accessible BET surface areas (S<sub>BET, N2</sub>; mN<sub>2</sub><sup>2</sup> g<sub>CAT</sub><sup>-1</sup>) and pore volumes (V<sub>PORE, N2</sub>; cmN<sub>2</sub><sup>3</sup> g<sub>CAT</sub><sup>-1</sup>) of the catalysts, respectively, for which the catalyst surfaces were purged at 150 °C under vacuum (2 X 10<sup>-3</sup> mmHg). The quantities of N<sub>2</sub> adsorbed on the catalyst surfaces at partial pressure (P/P<sub>0</sub>) domain of 0.05-0.3 were considered to assess S<sub>BET, N2</sub> values of the catalysts.<sup>7</sup> H<sub>2</sub>O isotherms of the catalysts were acquired on a BELSORP-MAX (MicrotracBEL Corp.) at 10-40 °C. H<sub>2</sub>O-accessible BET surface areas in a per-gram basis (S<sub>BET, H2O</sub>; mH<sub>2O</sub><sup>2</sup> g<sub>CAT</sub><sup>-1</sup>) or in a per-H<sub>2</sub>O-accessible site basis (S<sub>H2O</sub>; mH<sub>2O</sub><sup>2</sup> molH<sub>2O</sub><sup>-1</sup>) for the

catalysts were evaluated with the contemplation of the numbers of H<sub>2</sub>O adsorbed on the catalyst surfaces ( $N_{H_2O}$ ; mol<sub>H<sub>2</sub>O</sub> g<sub>CAT</sub><sup>-1</sup>) at P/P<sub>0</sub> domain of 0.05-0.3 and 10 °C.<sup>8-13</sup>  $S_{H_2O}$  values of the catalysts correspond to their  $S_{BET}$ ,  $H_2O$  values divided by  $N_{H_2O}$  values at P/P<sub>0</sub> of ~1.0 and 10 °C.<sup>10-15</sup> Moreover, H<sub>2</sub>O isotherms of the catalysts were fitted using Toth equation (Eqn. S1), in which  $N_{H_2O,0}$  is referred to as the maximum amount of H<sub>2</sub>O adsorbed in a per-gram of the catalyst (mol<sub>H<sub>2</sub>O</sub> g<sub>CAT</sub><sup>-1</sup>), whereas C, D, and P indicate constant indigenous to the catalyst (bar<sup>-1</sup>), constant associated with heterogeneity of the catalyst surface (unit-less), and pressure (bar), respectively,<sup>10-15</sup> as detailed in Table S7. Isothermic heats of H<sub>2</sub>O adsorption on the catalyst surfaces at near-zero H<sub>2</sub>O coverage ( $E_{H_2O}$ ) were evaluated using Clausius-Clapeyron equation (Eqn. S2), where  $P_A/P_B$  and R are referred to as pressures (bar) at temperatures of  $T_A/T_B$  (K) and ideal gas constant (8.3145 J mol<sup>-1</sup> K<sup>-1</sup>), respectively.<sup>10, 11, 14-16</sup>

$$N_{H_2O} = N_{H_2O,0} \times \frac{C \times P}{(1 + (C \times P)^D)^{1/D}} \quad (S1)$$

$$\ln\left(\frac{P_A}{P_B}\right) = \frac{E_{H_2O}}{R} \times \left(\frac{T_A - T_B}{T_A \times T_B}\right) \quad (S2)$$

Background-subtracted *in situ* diffuse reflectance infrared Fourier transform (DRIFT) spectra of the catalysts were acquired with the resolution of 4 cm<sup>-1</sup> on an FT/IR/4200 (Jasco) equipped with KBr optics and a mercury-cadmium-telluride (MCT) detector. The catalyst was placed in a reaction cell (Harrick Scientific), purged with 3 vol. % O<sub>2</sub>/N<sub>2</sub> at 300 °C for half an hour, and exposed to 250 °C (or 500 °C) under a N<sub>2</sub> for the collection of background signal at 250 °C (or 500 °C) with a ramping rate of 10 °C min<sup>-1</sup>. Background-subtracted *in situ* DRIFT spectrum of the catalyst was then collected under 1,000 ppm NH<sub>3</sub>/N<sub>2</sub> (at 250 °C), 1,000 ppm NO/3 vol. % O<sub>2</sub>/N<sub>2</sub> (at 250 °C) or under 1,000 ppm SO<sub>2</sub>/3 vol. % O<sub>2</sub>/N<sub>2</sub> (at 500 °C) with a total flow rate of 200 mL min<sup>-1</sup>. CO-pulsed chemisorption experiments of the catalysts were conducted on an Autochem II (Micromeritics) at 50 °C, for which 10 °C min<sup>-1</sup> served as a ramping rate. The catalyst surfaces were purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 50 °C under a He, and subjected to periodic CO injection at 50 °C till thermal conductivity detector (TCD) signals of CO were invariant.<sup>1-6</sup> O<sub>2</sub>-pulsed chemisorption experiments of the catalysts were also carried out on an Autochem II (Micromeritics) at 250 °C, for which 10 °C min<sup>-1</sup> served as a ramping rate.<sup>3</sup> The catalyst surfaces were purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 50 °C under a He, reduced under 10 vol. % H<sub>2</sub>/He at 300 °C for an hour, cooled to 250 °C under a He, and subjected to periodic O<sub>2</sub> injection at 250 °C till TCD signals of O<sub>2</sub> were unaltered.<sup>3</sup> O<sub>2</sub>-, NH<sub>3</sub>-, or SO<sub>2</sub>-temperature-programmed desorption (TPD) profiles of the catalysts were acquired on an Autochem II (Micromeritics), an Autochem II coupled with an on-line mass spectrometer (HPR20, Hiden Analytical), or an Autochem II connected to a quartz reactor coupled with an on-line SO<sub>2</sub> analyzer (ZKJ-2 (Fuji Electric Co.)). In the case of O<sub>2</sub>-TPD experiments with a ramping rate of 10 °C min<sup>-1</sup> except for that utilized during the final stage, the catalyst surface was purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 50 °C under a He, and reduced under 10 vol. % H<sub>2</sub>/He at 300 °C for an hour, cooled to 250 °C under a He, exposed to 10 vol. % O<sub>2</sub>/He at 250 °C for an hour to ensure the saturation of O<sub>2</sub>-accessible surface sites with O<sub>2</sub> prior to the exposure of the surface to a He at 250 °C for an hour to eliminate O<sub>2</sub> physisorbed on the surface.<sup>3</sup> The surface was finally heated to 600 °C under a He with a ramping rate ( $\beta$ ) of 10 °C min<sup>-1</sup>, 20 °C min<sup>-1</sup>, or 30 °C min<sup>-1</sup> for acquiring a profile of TCD signal of O<sub>2</sub> released versus temperature for the catalyst at a  $\beta$  value set.<sup>3-6, 17</sup> O<sub>2</sub>-TPD profiles at dissimilar  $\beta$  values were then curve-fitted using Gaussian function to reveal two sub-bands (denoted as I and II in Table S5) with desorption temperatures ( $T_{MAX}$ ), at which maximum intensities of TCD signals were observed.<sup>3-6, 17</sup> Binding energy between the surface and O<sub>2</sub> adsorbed ( $E_{OL/OM}$ ) was assessed with the use of TPD theory (Eqn. S3), where  $\theta_{OL/OM, MAX}$  and  $v_n/n$  are referred to as surface O<sub>2</sub> coverage at  $T_{MAX}$  and lumped constants indigenous to the surface, respectively.<sup>3-6, 17</sup> Plot of  $\ln(\beta/T_{MAX}^2)$  versus  $(1/T_{MAX})$  for sub-band I or II provided a slope identical to  $(-E_{OL/OM}/R)$  with the postulation concerning the independence of  $E_{OL/OM}$  on  $\theta_{OL/OM, MAX}$  (Table S5).<sup>3-6, 17</sup>

$$\ln\left(\frac{\beta}{T_{MAX}^2}\right) = -\left(\frac{E_{OL/OM}}{R}\right)\left(\frac{1}{T_{MAX}}\right) - 2.303 \times \log\left(\frac{E_{OL/OM}}{v_n R n \theta_{OL/OM, MAX}^{n-1}}\right) \quad (S3)$$

In the case of NH<sub>3</sub>-TPD experiments with NH<sub>3</sub> chemisorption at 150 °C and a ramping rate of 10 °C min<sup>-1</sup> except for that utilized during the final stage, the catalyst surface was purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an

hour, cooled to 150 °C under a He, exposed to 5 vol. % NH<sub>3</sub>/He at 150 °C for an hour to ensure the saturation of NH<sub>3</sub>-accessible surface sites with NH<sub>3</sub> prior to the exposure of the surface to a He at 150 °C for an hour to eliminate NH<sub>3</sub> physisorbed on the surface.<sup>3-6, 17</sup> The surface was finally heated to 700 °C under a He with a ramping rate ( $\beta$ ) of 10 °C min<sup>-1</sup>, 20 °C min<sup>-1</sup>, or 30 °C min<sup>-1</sup> for acquiring a profile of NH<sub>3</sub> ( $m/z \sim 17$ ) signal released versus temperature for the catalyst at a  $\beta$  value set.<sup>3-6, 17</sup> NH<sub>3</sub>-TPD profiles at dissimilar  $\beta$  values were then curve-fitted using Gaussian function to reveal three sub-bands (denoted as I, II, and III in Table S3) with desorption temperatures ( $T_{MAX}$ ), at which maximum intensities of NH<sub>3</sub> ( $m/z \sim 17$ ) signals were observed.<sup>3-6, 17</sup> Binding energy between the surface and NH<sub>3</sub> adsorbed ( $E_{NH_3}$ ) was assessed with the use of TPD theory (Eqn. S4), where  $\theta_{NH_3, MAX}$  and  $v_n/n$  are referred to as surface NH<sub>3</sub> coverage at  $T_{MAX}$  and lumped constants indigenous to the surface, respectively.<sup>3-6, 17</sup> Plot of  $\ln(\beta/T_{MAX}^2)$  versus  $(1/T_{MAX})$  for sub-band I, II, or III provided a slope identical to  $(-E_{NH_3}/R)$  with the postulation concerning the independence of  $E_{NH_3}$  on  $\theta_{NH_3, MAX}$  (Table S3).<sup>3-6, 17</sup>

$$\ln\left(\frac{\beta}{T_{MAX}^2}\right) = -\left(\frac{E_{NH_3}}{R}\right)\left(\frac{1}{T_{MAX}}\right) - 2.303 \times \log\left(\frac{E_{NH_3}}{v_n R n \theta_{NH_3, MAX}^{n-1}}\right) \quad (S4)$$

In the case of NH<sub>3</sub>-TPD experiments with NH<sub>3</sub> chemisorption at 50 °C and a ramping rate of 10 °C min<sup>-1</sup>, the catalyst surface was purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 50 °C under a He, exposed to 5 vol. % NH<sub>3</sub>/He at 50 °C for an hour to ensure the saturation of NH<sub>3</sub>-accessible surface sites with NH<sub>3</sub> prior to the exposure of the surface to a He at 50 °C for an hour to eliminate NH<sub>3</sub> physisorbed on the surface. The surface was finally heated to 700 °C under a He for acquiring a profile of NH<sub>3</sub> ( $m/z \sim 17$ ) signal released versus temperature for the catalyst. In the case of SO<sub>2</sub>-TPD experiment with SO<sub>2</sub> chemisorption at 220 °C and a ramping rate of 10 °C min<sup>-1</sup>, the catalyst surface was purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 220 °C under a He, exposed to 5,000 ppm SO<sub>2</sub>/N<sub>2</sub> at 220 °C for an hour to ensure the saturation of SO<sub>2</sub>-accessible surface sites with SO<sub>2</sub> prior to the exposure of the surface to a He at 220 °C for an hour to eliminate SO<sub>2</sub> physisorbed on the surface. The surface was finally heated to 900 °C under a He for acquiring a profile of SO<sub>2</sub> concentration released versus temperature for the catalyst. H<sub>2</sub>-temperature-programmed reduction (TPR) profiles of the catalysts were acquired on an Autochem II (Micromeritics). While a ramping rate was set to 10 °C min<sup>-1</sup>, the catalyst surface was purged with 10 vol. % O<sub>2</sub>/He at 300 °C for an hour, cooled to 50 °C under a He, and reduced to 900 °C under 10 vol. % H<sub>2</sub>/He for acquiring a profile of TCD signal versus temperature for the catalyst. A thermo-gravimetric analyzer (TGA2, Mettler-Toledo, denoted as TGA) equipped with an on-line mass spectrometer (HPR20, Hiden Analytical, denoted as MASS) were utilized to conduct TGA-MASS experiments of the catalysts poisoned with AS/ABS.<sup>2, 4</sup> The poisoned catalyst was situated in an Al<sub>2</sub>O<sub>3</sub> pan, purged with an Ar at 100 °C for an hour, and heated to 600 °C under an Ar with a flow rate of 50 mL min<sup>-1</sup> and a ramping rate of 2 °C min<sup>-1</sup> for acquiring a series of profiles concerning weight loss/NH<sub>3</sub> signal ( $m/z \sim 17$ )/H<sub>2</sub>O signal ( $m/z \sim 18$ )/SO<sub>2</sub> signal ( $m/z \sim 64$ ) released versus temperature for the catalyst.<sup>2, 4</sup>

## Reactions

Initially, the catalyst sieved with sizes of 200-300  $\mu\text{m}$  or 300-425  $\mu\text{m}$  was placed inside a quartz reactor with an inner diameter of 0.4 cm, wherein the amount of the catalyst loaded was altered to regulate the control volume and/or space velocity (e.g., 0.31 g/0.62 g of catalyst  $\rightarrow$  0.5 mL/1 mL of control volume  $\rightarrow$  60,000 hr<sup>-1</sup>/30,000 hr<sup>-1</sup> of space velocity). The quartz reactor was then loaded in a tube furnace, purged with 3 vol. % O<sub>2</sub>/N<sub>2</sub> at 400 °C for an hour, and subjected to control SCR or SO<sub>2</sub> oxidation runs under a feed gas stream including N<sub>2</sub>, NO<sub>x</sub>, NH<sub>3</sub>, O<sub>2</sub>, H<sub>2</sub>O, or SO<sub>2</sub> with variable compositions alongside with the use of a total flow rate of 500 mL min<sup>-1</sup> and a reaction temperature of  $\leq$  400 °C. Effluents emitted from the control volume were monitored using ZKJ-2 (Fuji Electric Co.) for NO/SO<sub>2</sub>, Ultramat 6 (Siemens Co.) for N<sub>2</sub>O, and detector tubes (GASTEC Co.) for NO<sub>2</sub>/NH<sub>3</sub>. NO<sub>x</sub> conversion ( $X_{NO_x}$ ) and N<sub>2</sub> selectivity ( $S_{N_2}$ ) of the catalyst were evaluated using Eqn. S5 and S6, wherein  $C_{YYY, IN}$  and  $C_{YYY, OUT}$  are referred to as concentrations of species YYY at the inlet (IN) and outlet (OUT), respectively.

$$X_{NO_x} (\%) = \frac{C_{NO, IN} - C_{NO, OUT} - C_{NO_2, OUT} - 2 \times C_{N_2O, OUT}}{C_{NO, IN}} \times 100 \quad (S5)$$

$$S_{N_2} (\%) = \frac{C_{NO,IN} + C_{NH_3,IN} - C_{NO,OUT} - C_{NH_3,OUT} - C_{NO_2,OUT} - 2 \times C_{N_2O,OUT}}{C_{NO,IN} + C_{NH_3,IN} - C_{NO,OUT} - C_{NH_3,OUT}} \times 100 \quad (S6)$$

NO<sub>x</sub> consumption rate ( $-r_{NOx}$ ) in a per-NH<sub>3</sub>-accessible site for the catalyst was evaluated using Eqn. S7, in which the quantity of NH<sub>3</sub>-accessible sites in a per-gram of the catalyst ( $N_{NH_3}$ ) can be evaluated via its NH<sub>3</sub>-TPD experiment with NH<sub>3</sub> chemisorption at 150 °C (Table S4).<sup>2-4, 6, 17</sup>  $-r_{NOx}$  generically corresponds to Eqn. S8, in which  $k_{APP}$  and  $C_{NOx}$ ,  $C_{NH_3}$ ,  $C_{O_2}$  indicate the apparent reaction rate constant, NO<sub>x</sub> concentration, NH<sub>3</sub> concentration, and O<sub>2</sub> concentration, respectively, whereas  $\alpha/\beta/\gamma$  denote the reaction orders with respect to NO<sub>x</sub>/NH<sub>3</sub>/O<sub>2</sub>.<sup>3, 4, 6</sup> Arrhenius plot of  $\ln(-r_{NOx})$  versus  $1/T_{REACTION}$  for the catalyst (Eqn. S9) provides a slope ( $-E_{BARRIER}/R$ ) and y-intercept ( $\ln(k_{APP,0} C_{NOx}^\alpha C_{NH_3}^\beta C_{O_2}^\gamma)$ ), by which the energy barrier ( $E_{BARRIER}$ ) and lumped pre-factor ( $k_{APP,0} C_{NOx}^\alpha C_{NH_3}^\beta C_{O_2}^\gamma$ ;  $k'_{APP,0}$ ) required to proceed with SCR are evaluated at reaction temperatures ( $T_{REACTION}$ ) considered, respectively.<sup>3, 4, 6</sup>

$$-r_{NOx} (\text{min}^{-1}) = \frac{\text{moles of NO}_x \text{ reduced per gram of the catalyst per unit time } (\Delta \text{mol}_{NOx} \text{ g}_{CAT}^{-1} \text{ min}^{-1})}{N_{NH_3} (\text{mol}_{NH_3} \text{ g}_{CAT}^{-1})} \quad (S7)$$

$$-r_{NOx} (\text{min}^{-1}) = k_{APP} C_{NOx}^\alpha C_{NH_3}^\beta C_{O_2}^\gamma \quad (S8)$$

$$\ln(-r_{NOx}) = \left(-\frac{E_{BARRIER}}{R}\right) \times \left(\frac{1}{T_{REACTION}}\right) + \ln \left(\frac{k_{APP,0} C_{NOx}^\alpha C_{NH_3}^\beta C_{O_2}^\gamma}{\text{lumped pre-factor}}\right) \quad (S9)$$

AS/ABS degradation rate ( $-r_{AS/ABS}$ ) in a per-NH<sub>3</sub>-accessible site for the catalyst was assessed using Eqn. S10, for which weight lost above NH<sub>3</sub> onset temperature presumably originates from ABS degradation, whereas  $N_{NH_3}$  was contemplated because NH<sub>3</sub>-accessible sites were identified to function as major active species in catalyzing AS/ABS degradation.<sup>4</sup> In addition, TGA-MASS data above SO<sub>2</sub> onset temperature was also considered for the evaluation of  $-r_{AS/ABS}$  for the catalyst, given the rate-determining stage of catalytic AS/ABS degradation pathway we reported elsewhere (*i.e.*, H<sub>2</sub>-assisted dissociative desorption of H<sup>+</sup>••O-SO<sub>2</sub>-O••H<sup>+</sup> from B<sup>-</sup>-H<sup>+</sup>••O-SO<sub>2</sub>-O••H<sup>+</sup>, where B<sup>-</sup> denote conjugate base of Brönsted acidic bond (B-H<sup>+</sup>) in Fig. 1D).<sup>4</sup> In this regard, weight lost at 260 °C, 270 °C, 280 °C, or 290 °C with temperature deviation of  $\pm \sim 0.5$  °C (time interval ( $\Delta t$ ) of  $\leq \sim 0.5$  minutes) was considered to assess  $-r_{AS/ABS}$  of the catalyst (Table S8).<sup>4</sup>  $-r_{AS/ABS}$  can be expressed using a generic n<sup>th</sup>-order reaction rate law, where  $k_{AS/ABS, APP}$  and  $C_{AS/ABS}$  denote apparent reaction rate constant and AS/ABS concentration, respectively.<sup>4</sup> Arrhenius plot of  $\ln(-r_{AS/ABS})$  versus  $1/T_{REACTION}$  for the catalysts (Eqn. S11) provides a slope ( $-E_{BARRIER}/R$ ) and y-intercept ( $\ln(k_{AS/ABS, APP,0} C_{AS/ABS}^n)$ ), in which  $E_{BARRIER}$  and  $k_{AS/ABS, APP,0}$  indicate the energy barrier and lumped pre-factor needed to proceed with AS/ABS degradation at  $T_{REACTION}$  values considered, respectively.<sup>4</sup>

$$-r_{AS/ABS} (\text{min}^{-1}) = \frac{\text{moles of ABS decomposed per gram of the catalyst } (\Delta \text{mol}_{ABS} \text{ g}_{CAT}^{-1})}{N_{NH_3} \text{ of catalyst } (\text{mol}_{NH_3} \text{ g}_{CAT}^{-1}) \times \text{time interval } (\Delta t) \text{ used to measure } \Delta \text{mol}_{ABS} \text{ g}_{CAT}^{-1} (\text{min})} \quad (S10)$$

$$\ln(-r_{AS/ABS}) = \left(-\frac{E_{BARRIER}}{R}\right) \times \left(\frac{1}{T_{REACTION}}\right) + \ln \left(\frac{k_{AS/ABS, APP,0} C_{AS/ABS}^n}{\text{lumped pre-factor}}\right) \quad (S11)$$

Cu <sub>3</sub> V <sub>2</sub> O <sub>8</sub>	220	30,000	~16 hours	<sup>3</sup>
Ni <sub>1</sub> V <sub>2</sub> O <sub>6</sub>	220	30,000	~53 hours	this work

<sup>a</sup> SO<sub>2</sub><sup>2-</sup> functionalization conditions: 500 ppm SO<sub>2</sub>; 3 vol. % O<sub>2</sub>; catalysts with the sizes with 300-425 μm; space velocity of 60,000 hr<sup>-1</sup>; total flow rate of 500 ml min<sup>-1</sup>; ramping rate of 10 °C min<sup>-1</sup>; 500 °C for an hour; balanced by a N<sub>2</sub>. <sup>b</sup> supported on Sb/TiO<sub>2</sub> with Sb contents of 3 wt. %. <sup>c</sup> reaction condition: 800 ppm NO<sub>x</sub>; 800 ppm NH<sub>3</sub>; 500 ppm SO<sub>2</sub>; 3 vol. % O<sub>2</sub>; 5.4 vol. % H<sub>2</sub>O (for Mn<sub>1</sub>V<sub>2</sub>O<sub>6</sub>) or 6 vol. % H<sub>2</sub>O (for Cu<sub>3</sub>V<sub>2</sub>O<sub>8</sub>); catalysts with the sizes with 300-425 μm; total flow rate of 500 ml min<sup>-1</sup>, balanced by a N<sub>2</sub>.

**Fig. S1.**  $N_2$  isotherms of the catalysts ( $Ni_1$  for A;  $Ni_2$  for C;  $Ni_3$  for E;  $Ni_1-Sb$  for G) and those functionalized with  $SO_4^{2-}/HSO_4^-$  ( $Ni_1-S$  for B;  $Ni_2-S$  for D;  $Ni_3-S$  for F;  $Ni_1-Sb-S$  for H).

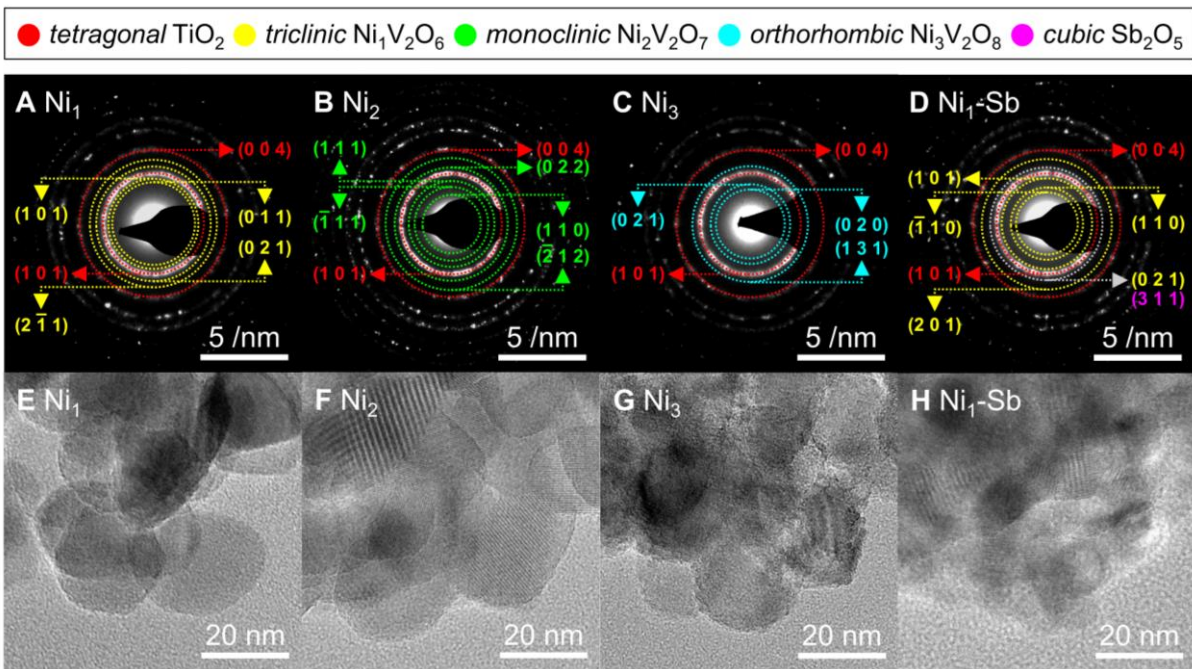

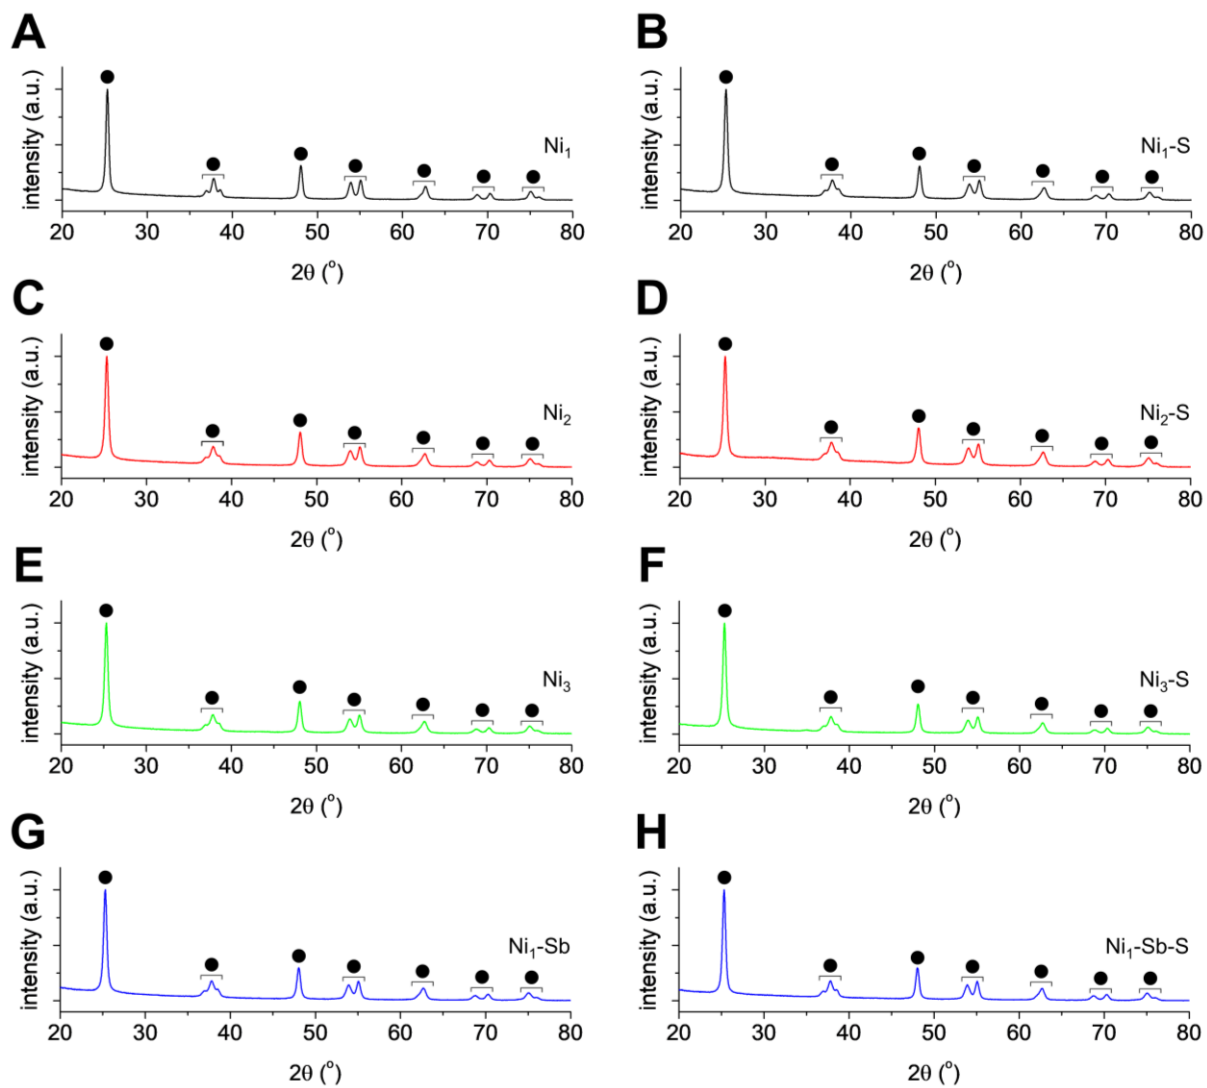

**Fig. S2.** Full scan survey of the XPS spectra for the catalysts ( $\text{Ni}_1$  for A;  $\text{Ni}_2$  for C;  $\text{Ni}_3$  for E;  $\text{Ni}_1\text{-Sb}$  for G) and those functionalized with  $\text{SO}_4^{2-}/\text{HSO}_4^-$  ( $\text{Ni}_1\text{-S}$  for B;  $\text{Ni}_2\text{-S}$  for D;  $\text{Ni}_3\text{-S}$  for F;  $\text{Ni}_1\text{-Sb-S}$  for H). In (G-H), albeit with substantial overlaps between Sb 3d  $_{5/2}$  and O 1s regimes at binding energies of 525.0-535.0 eV,<sup>3,4,6</sup> surface O compositions were in marked excess relative to their surface Sb counterparts. This thus made it highly sound that the XPS spectra of  $\text{Ni}_1\text{-Sb}$  and  $\text{Ni}_1\text{-Sb-S}$  at binding energies of 525.0-535.0 eV could be dictated by O of chemisorbed  $\text{H}_2\text{O}$ , labile O, and lattice O species.<sup>4</sup>

**Fig. S3.** EDX mapping images of the catalysts (Ni<sub>1</sub> for A-E; Ni<sub>2</sub> for F-J; Ni<sub>3</sub> for K-O; Ni<sub>1</sub>-Sb for P-U).

**Fig. S4.** SAED patterns (A-D) and HRTEM images (E-H) of the catalysts ( $\text{Ni}_1$  for A and E;  $\text{Ni}_2$  for B and F;  $\text{Ni}_3$  for C and G;  $\text{Ni}_1\text{-Sb}$  for D and H). In (A-D), dashed circles indicate surface diffractions indexed to those of *tetragonal*  $\text{TiO}_2$  (anatase, JCPDF No. of 01-071-1166), *triclinc*  $\text{Ni}_1\text{V}_2\text{O}_6$  (JCPDF No. of 01-076-0359), *monoclinic*  $\text{Ni}_2\text{V}_2\text{O}_7$  (JCPDF No. of 00-038-0285), *orthorhombic*  $\text{Ni}_3\text{V}_2\text{O}_8$  (JCPDF No. of 01-070-2392), or *cubic*  $\text{Sb}_2\text{O}_5$  (JCPDF No. of 00-011-0690). Surface diffractions with  $d$  spacing values of  $< 2.37 \text{ \AA}$  were not assigned due to significant overlaps among the diffractions of  $\text{TiO}_2$ ,  $\text{Ni}_1\text{V}_2\text{O}_6$ ,  $\text{Ni}_2\text{V}_2\text{O}_7$ ,  $\text{Ni}_3\text{V}_2\text{O}_8$ , or  $\text{Sb}_2\text{O}_5$ .

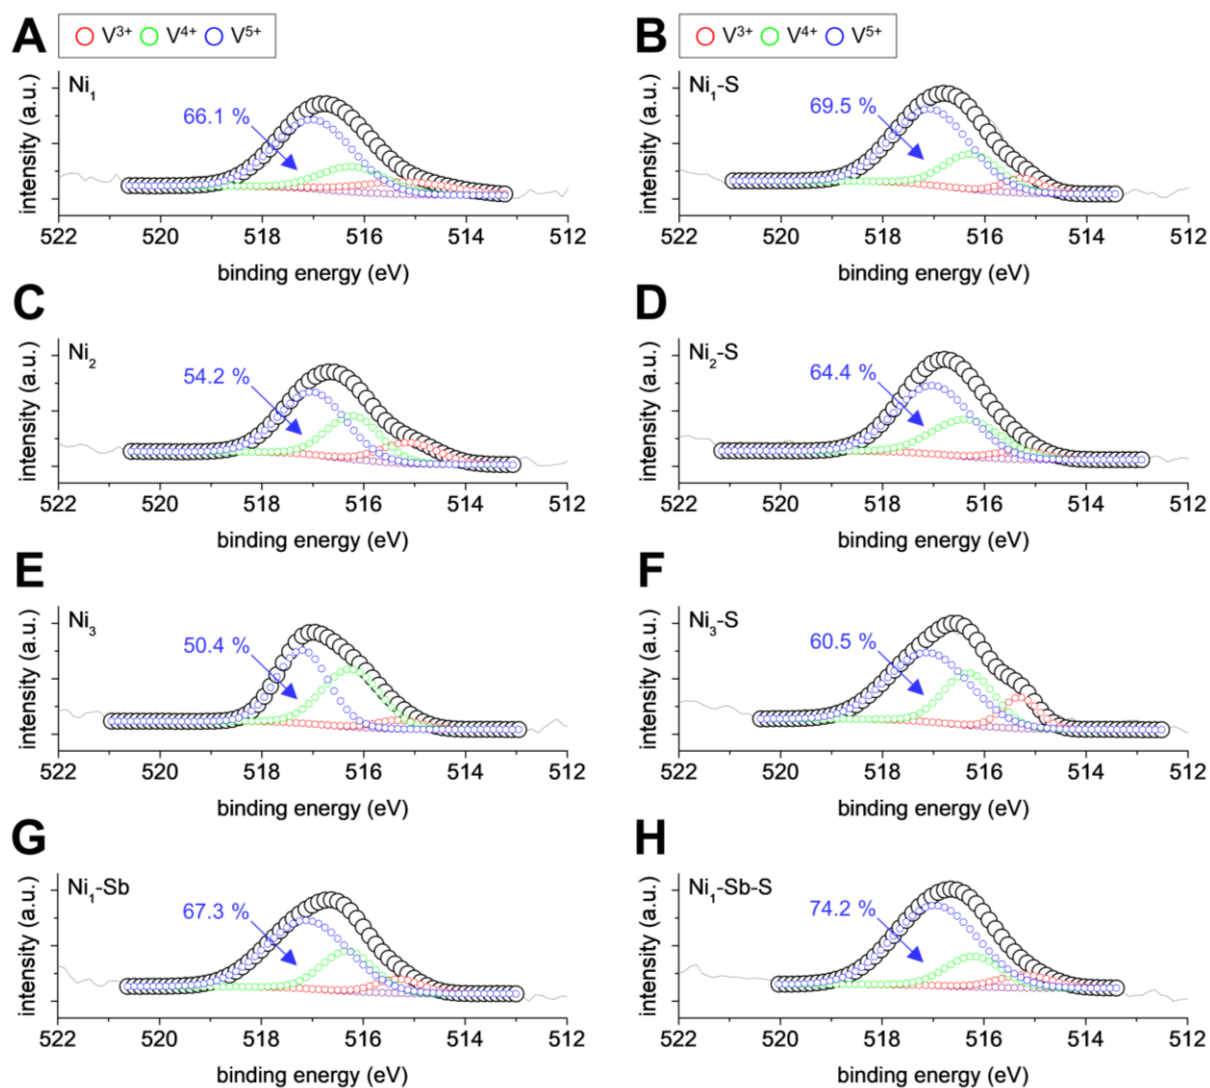

**Fig. S5.** XRD patterns of the catalysts ( $\text{Ni}_1$  for A;  $\text{Ni}_2$  for C;  $\text{Ni}_3$  for E;  $\text{Ni}_1\text{-Sb}$  for G) and those functionalized with  $\text{SO}_4^{2-}/\text{HSO}_4^-$  ( $\text{Ni}_1\text{-S}$  for B;  $\text{Ni}_2\text{-S}$  for D;  $\text{Ni}_3\text{-S}$  for F;  $\text{Ni}_1\text{-Sb-S}$  for H). In (A-H), black solid circles denote bulk diffractions assigned to those of *tetragonal*  $\text{TiO}_2$  (anatase, JCPDF No. of 01-071-1166).

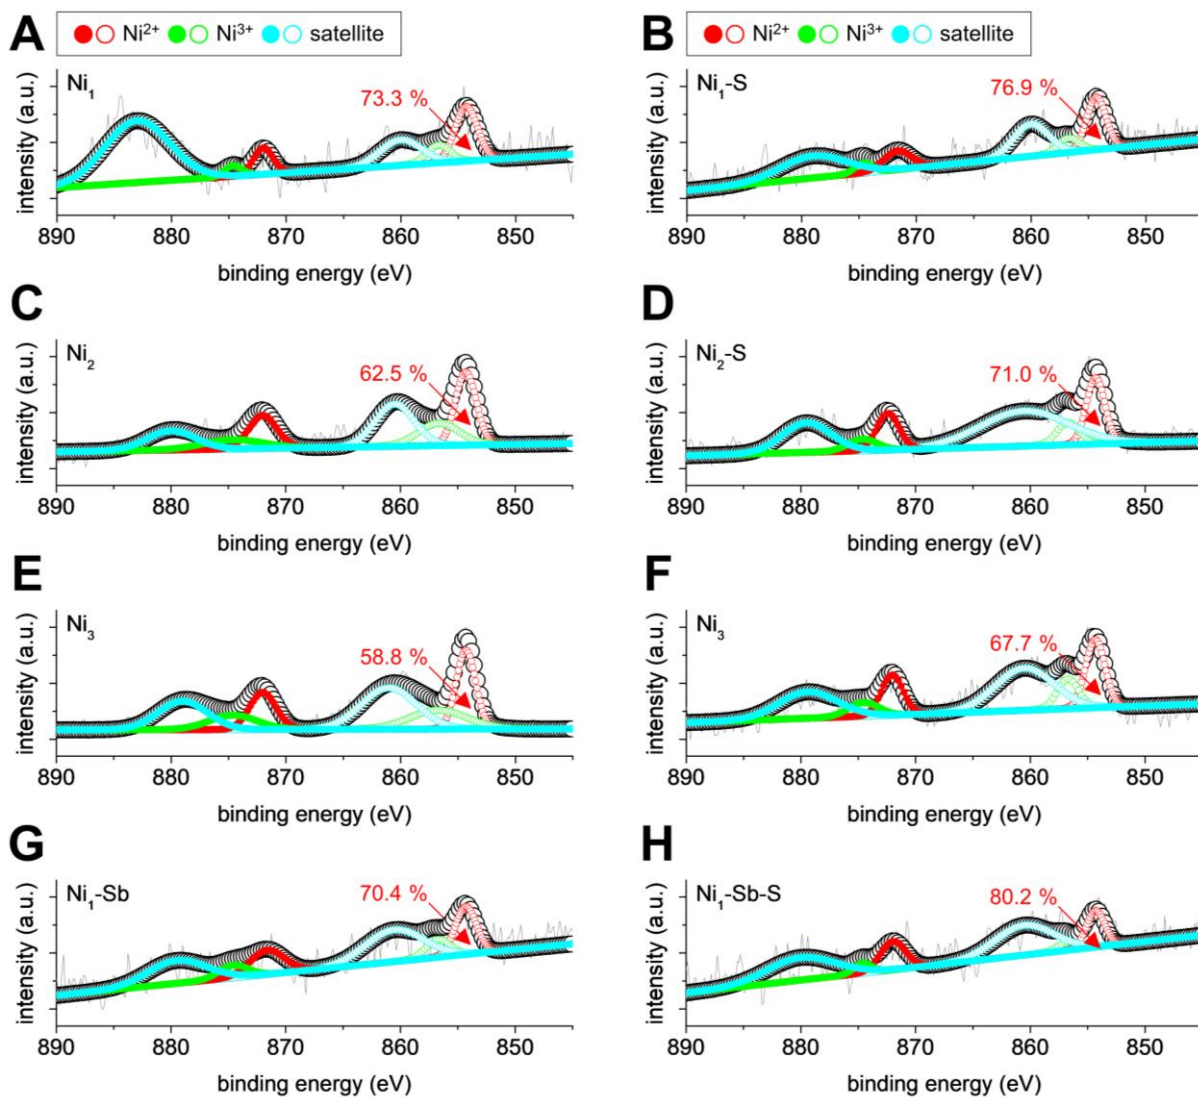

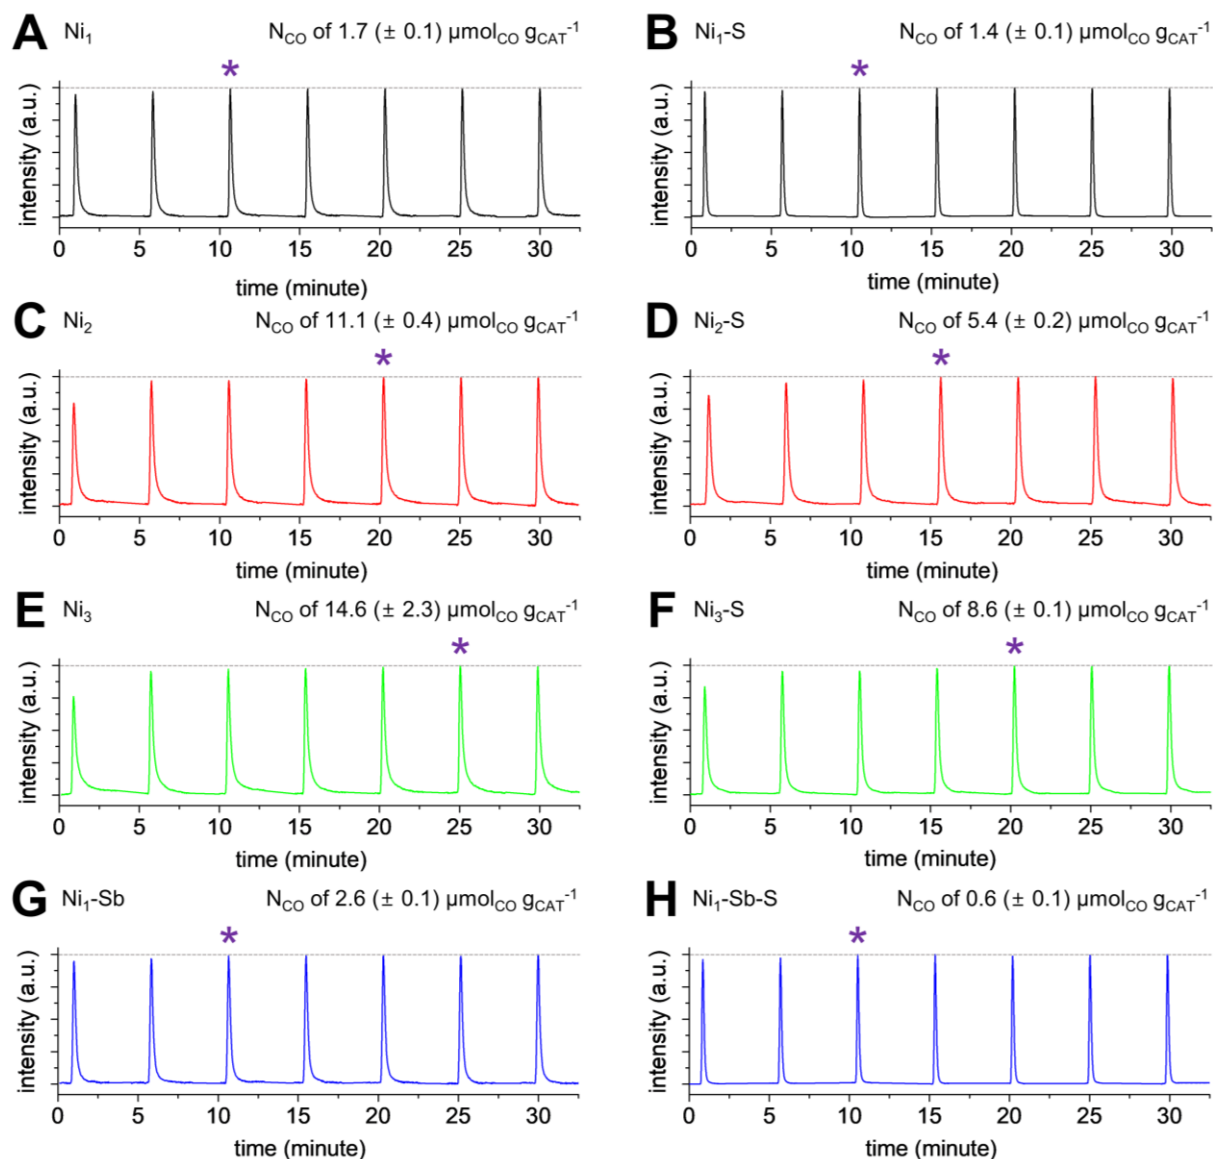

**Fig. S6.** EDX mapping images of the catalysts ( $\text{Ni}_1\text{-S}$  for A-F;  $\text{Ni}_2\text{-S}$  for G-L;  $\text{Ni}_3\text{-S}$  for M-R;  $\text{Ni}_1\text{-Sb-S}$  for S-Y).

**Fig. S7.** XPS spectra of the catalysts ( $\text{Ni}_1$  for A;  $\text{Ni}_2$  for C;  $\text{Ni}_3$  for E;  $\text{Ni}_1\text{-Sb}$  for G) and those functionalized with  $\text{SO}_2^{2-}/\text{HSO}_2^-$  ( $\text{Ni}_1\text{-S}$  for B;  $\text{Ni}_2\text{-S}$  for D;  $\text{Ni}_3\text{-S}$  for F;  $\text{Ni}_1\text{-Sb-S}$  for H) in the V 2p domains. In (A-H), gray solid lines and black empty circles denote raw and fitted spectra, respectively, whereas purple empty circles indicate backgrounds. In addition, red, green, and blue empty circles denote surface  $\text{V}^{3+}$ ,  $\text{V}^{4+}$ , and  $\text{V}^{5+}$  phases, respectively.

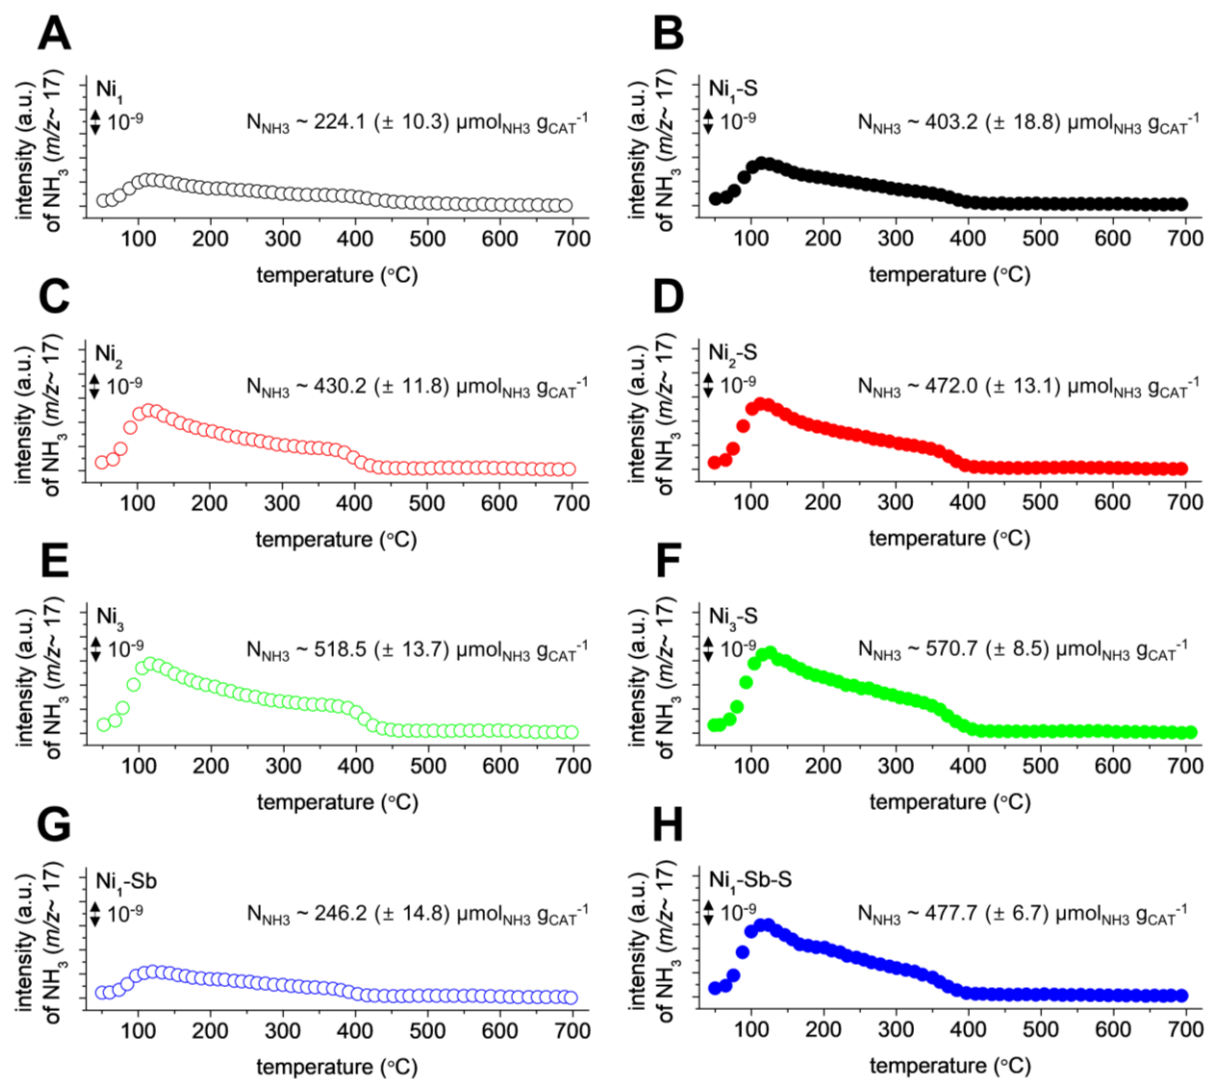

**Fig. S8.** XPS spectra of the catalysts (Ni<sub>1</sub> for A; Ni<sub>2</sub> for C; Ni<sub>3</sub> for E; Ni<sub>1</sub>-Sb for G) and those functionalized with SO<sub>2</sub><sup>2-</sup>/HSO<sub>3</sub><sup>-</sup> (Ni<sub>1</sub>-S for B; Ni<sub>2</sub>-S for D; Ni<sub>3</sub>-S for F; Ni<sub>1</sub>-Sb-S for H) in the Ni 2p domains. In (A-H), gray solid lines and black empty circles denote raw and fitted spectra, respectively, whereas purple empty circles indicate backgrounds. In addition, red/green/cyan solid and empty circles denote surface Ni<sup>2+</sup>/Ni<sup>3+</sup>/satellite in the Ni 2p<sub>1/2</sub> and Ni 2p<sub>3/2</sub> regimes, respectively.

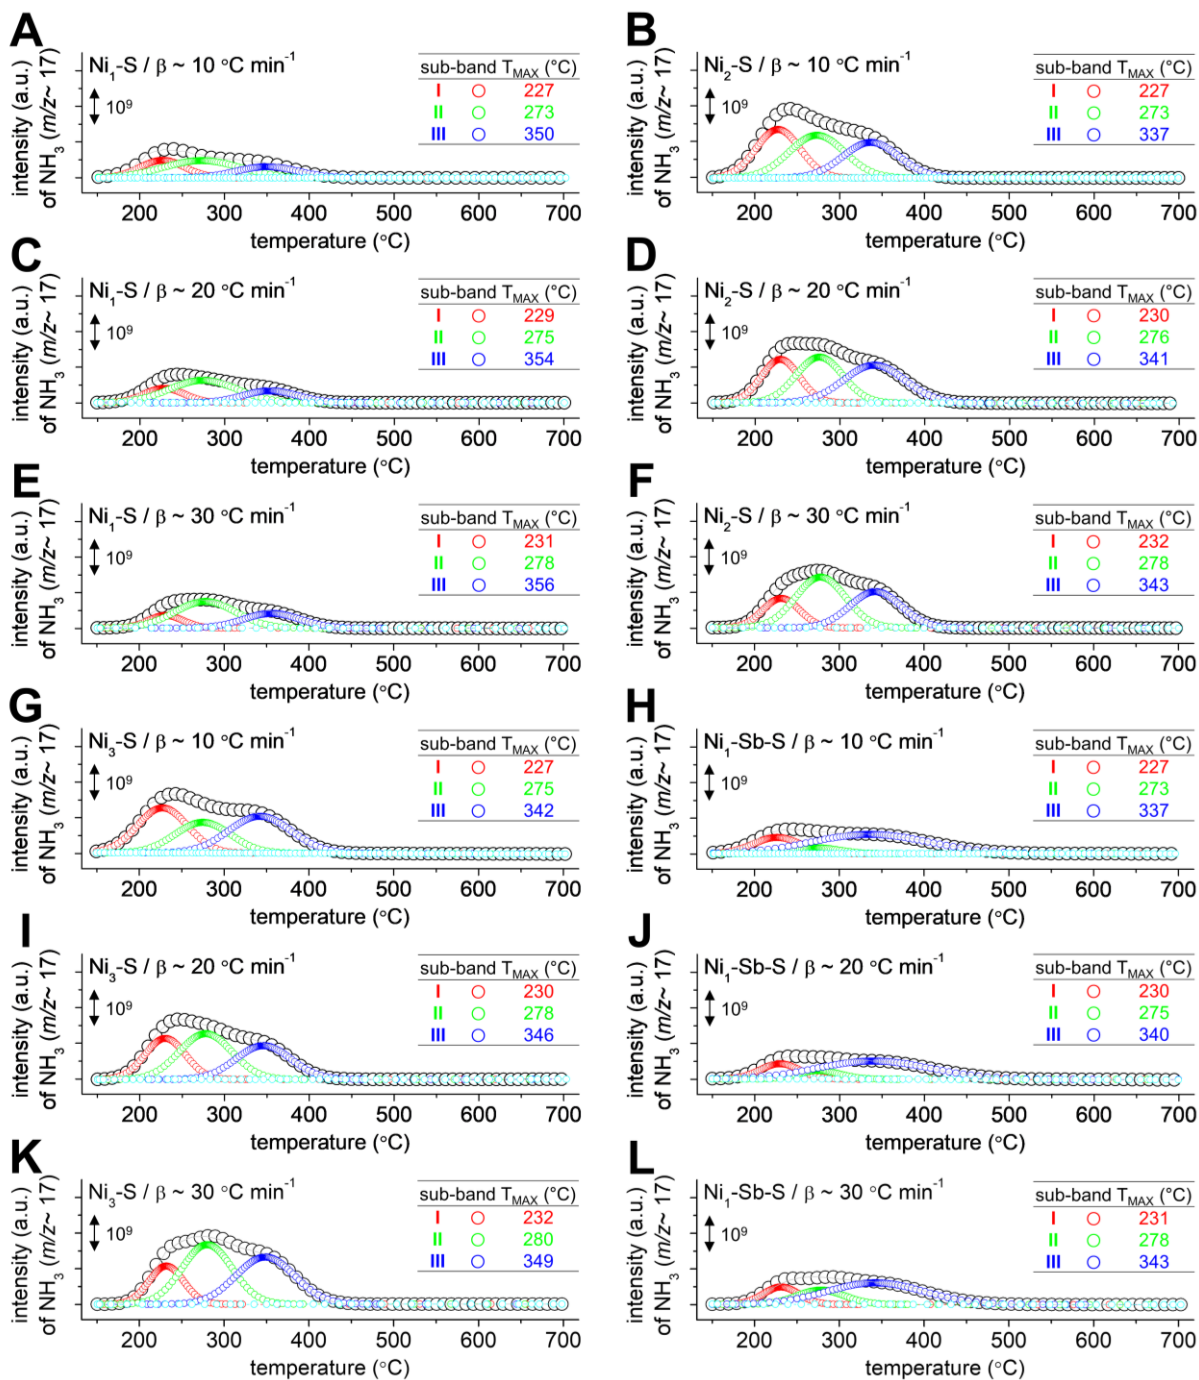

**Fig. S9.** CO-pulsed chemisorption profiles of the catalysts (Ni<sub>1</sub> for A; Ni<sub>2</sub> for C; Ni<sub>3</sub> for E; Ni<sub>1</sub>-Sb for G) and those functionalized with SO<sub>4</sub><sup>2-</sup>/HSO<sub>4</sub><sup>-</sup> (Ni<sub>1</sub>-S for B; Ni<sub>2</sub>-S for D; Ni<sub>3</sub>-S for F; Ni<sub>1</sub>-Sb-S for H) at 50 °C. In (A-G), \* corresponds to the onset of TCD signals for CO, whose intensities were almost invariant.

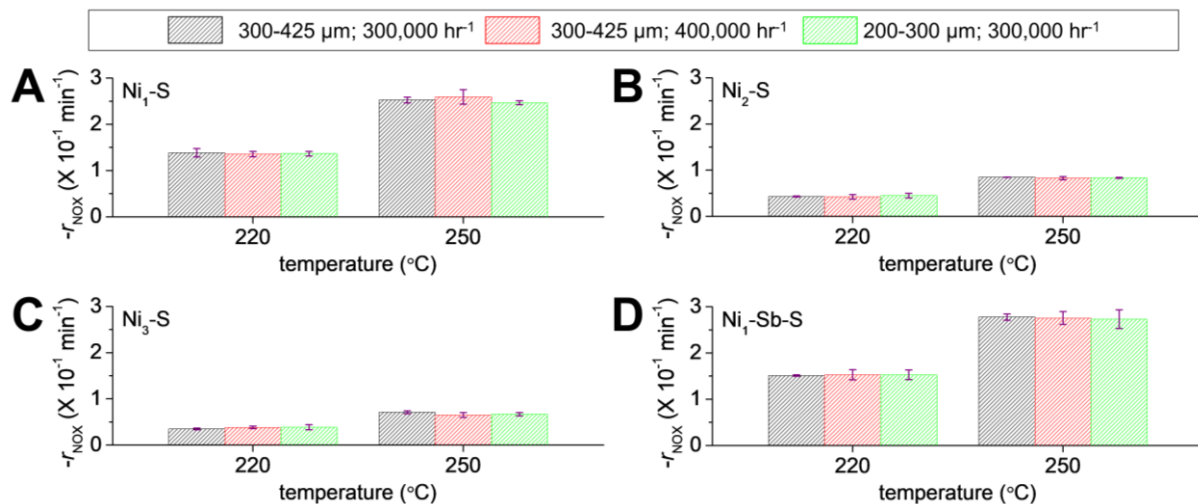

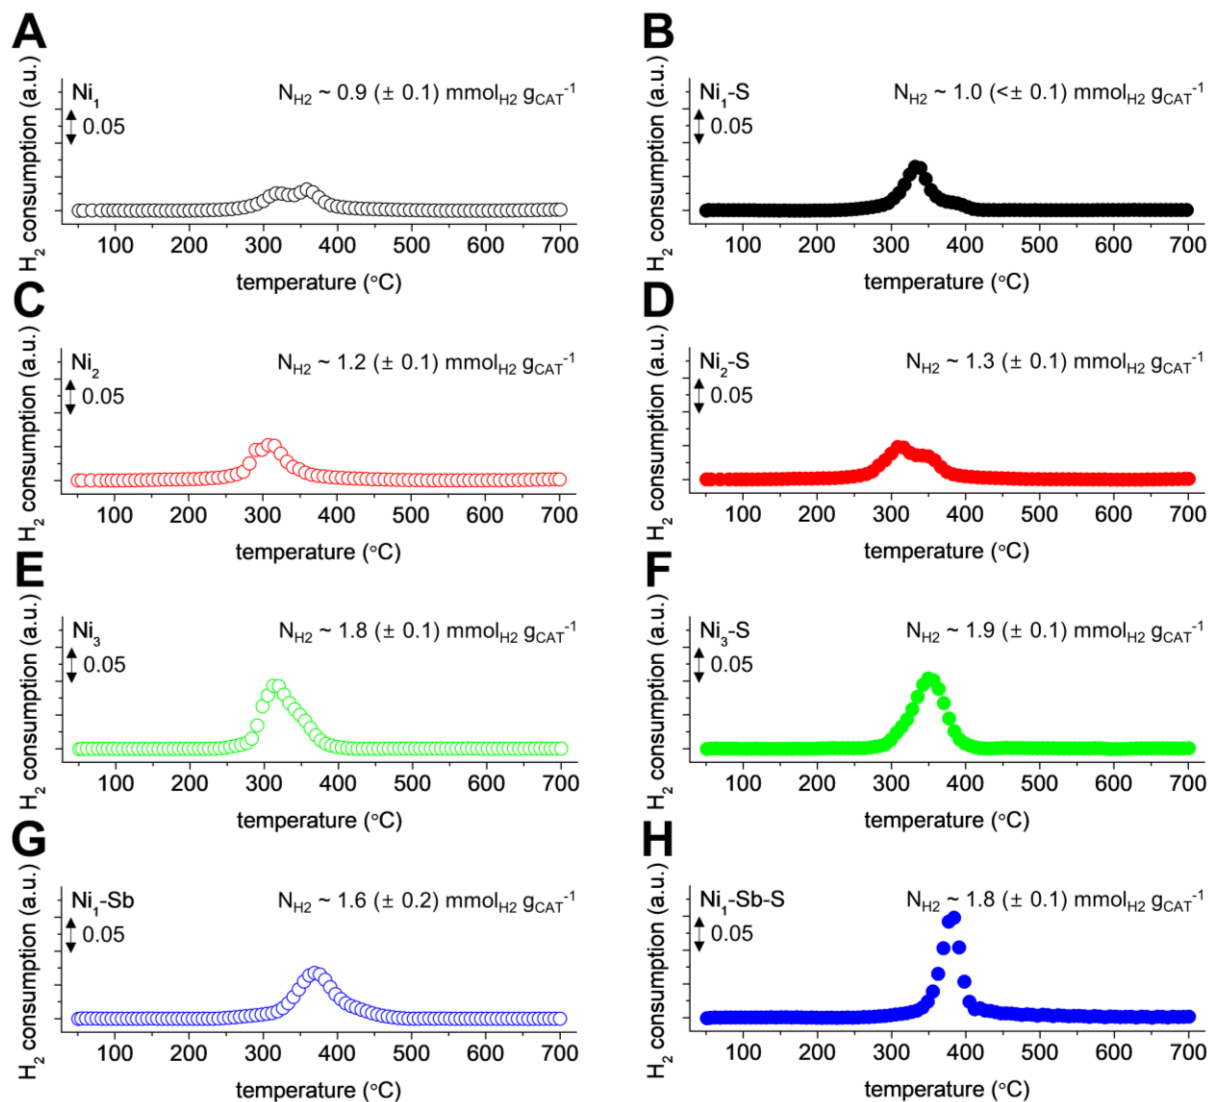

**Fig. S10.**  $\text{NH}_3$ -TPD profiles ( $\text{NH}_3$  signal versus temperature) of the catalysts ( $\text{Ni}_1$  for A;  $\text{Ni}_2$  for C;  $\text{Ni}_3$  for E;  $\text{Ni}_1\text{-Sb}$  for G) and those functionalized with  $\text{SO}_4^{2-}/\text{HSO}_4^-$  ( $\text{Ni}_1\text{-S}$  for B;  $\text{Ni}_2\text{-S}$  for D;  $\text{Ni}_3\text{-S}$  for F;  $\text{Ni}_1\text{-Sb-S}$  for H). The catalyst surfaces chemisorbed  $\text{NH}_3$  at 50 °C and were then heated to 700 °C with a ramping rate of 10 °C  $\text{min}^{-1}$ . In (A-H),  $N_{\text{NH}_3}$  values indicate the numbers of  $\text{NH}_3$  adsorbed in a per-gram of the catalysts at 50 °C.

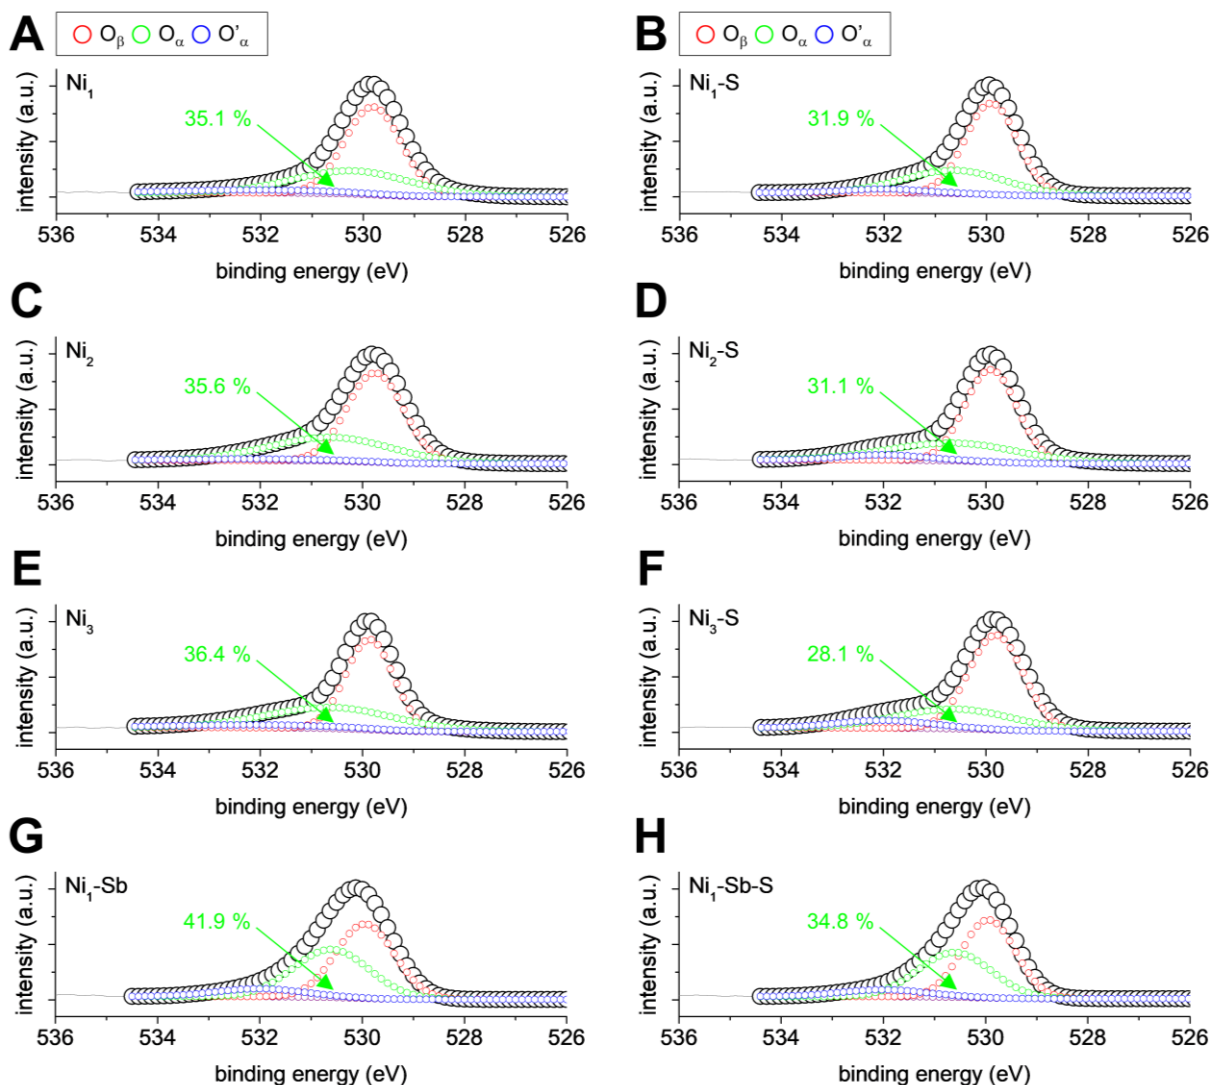

**Fig. S11.**  $\text{NH}_3$ -TPD profiles ( $\text{NH}_3$  signal versus temperature) of the catalysts functionalized with  $\text{SO}_z^{2-}/\text{HSO}_z^-$  ( $\text{Ni}_1$ -S for A, C, and E;  $\text{Ni}_2$ -S for B, D, and F;  $\text{Ni}_3$ -S for G, I, and K;  $\text{Ni}_1$ -Sb-S for H, J, and L). The catalyst surfaces chemisorbed  $\text{NH}_3$  at 150 °C and were then heated to 700 °C with a ramping rate ( $\beta$ ) of 10 °C  $\text{min}^{-1}$  (A, B, G, and H), 20 °C  $\text{min}^{-1}$  (C, D, I, and J), or 30 °C  $\text{min}^{-1}$  (E, F, K, and L). In (A-L),  $\text{NH}_3$ -TPD profiles were de-convoluted using Gaussian function to reveal backgrounds (cyan empty circles) and three sub-bands (I (red empty circle), II (green empty circle), and III (blue empty circle)), whose temperatures with maximum  $\text{NH}_3$  signal intensities ( $T_{\text{MAX}}$ ) are presented in inset tables and served to assess  $\text{NH}_3$  binding energies ( $E_{\text{NH}_3}$ ) of the catalyst surfaces at 150 °C.

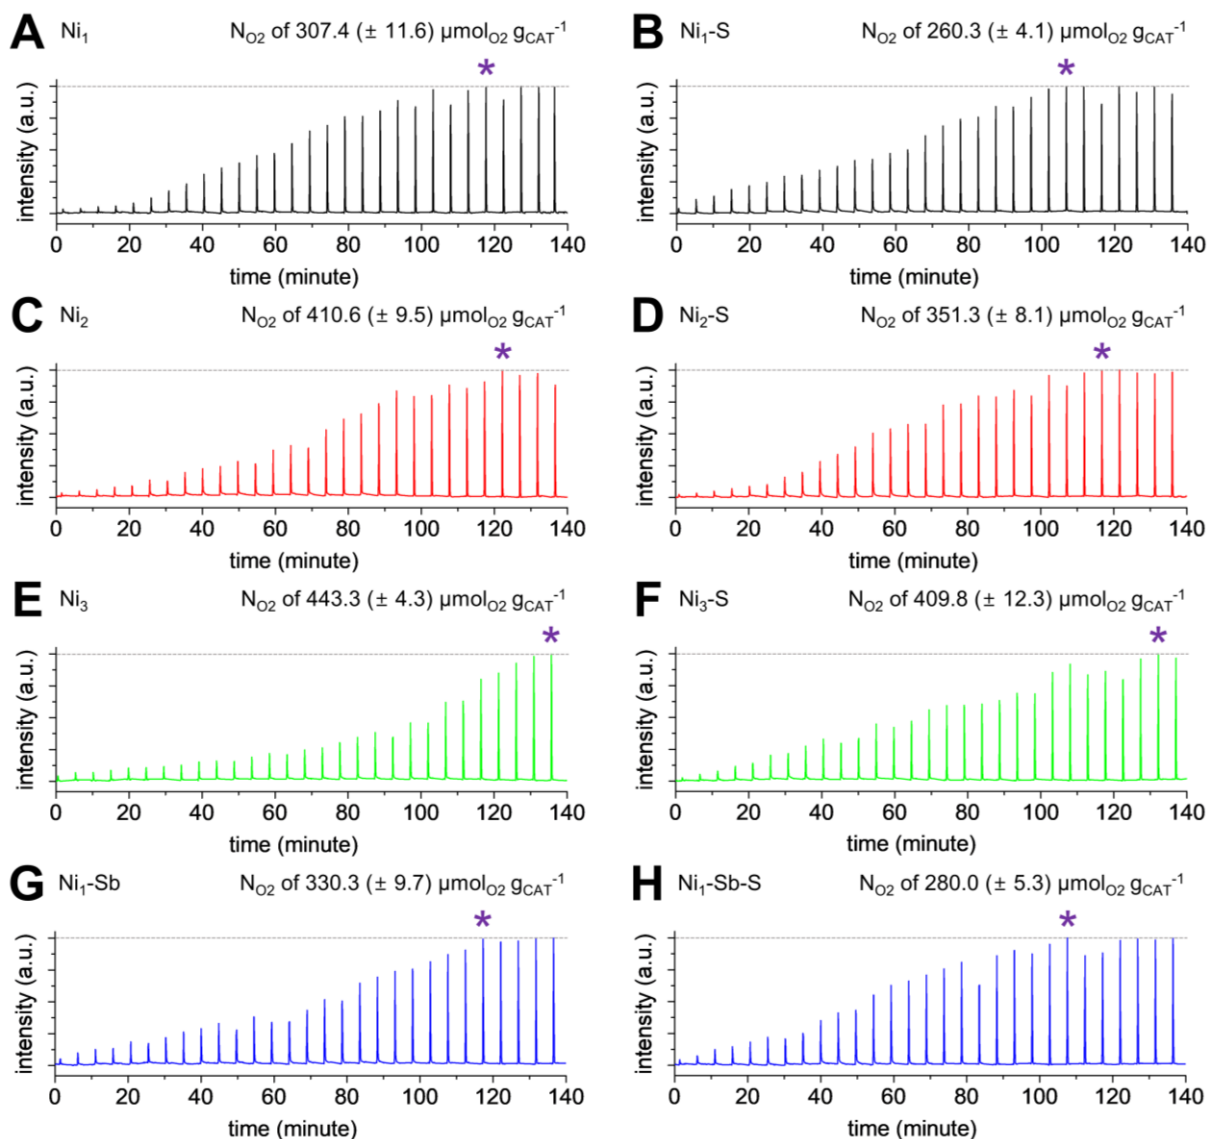

**Fig. S12.**  $\text{NO}_x$  consumption rates ( $-r_{\text{NO}_x}$ ) of the catalysts upon the change in their particle sizes (200-300  $\mu\text{m}$  or 300-425  $\mu\text{m}$ ) or space velocities (300,000  $\text{hr}^{-1}$  or 400,000  $\text{hr}^{-1}$ ) at 220 and 250  $^{\circ}\text{C}$  ( $\text{Ni}_1\text{-S}$  for A;  $\text{Ni}_2\text{-S}$  for B;  $\text{Ni}_3\text{-S}$  for C;  $\text{Ni}_1\text{-Sb-S}$  for D). SCR conditions: 800 ppm  $\text{NO}_x$ ; 800 ppm  $\text{NH}_3$ ; 3 vol. %  $\text{O}_2$ ; 5.4 vol. %  $\text{H}_2\text{O}$ ; total flow rate of 500  $\text{mL min}^{-1}$ ; balanced by a  $\text{N}_2$ .

**Fig. S13.** H<sub>2</sub>-TPR profiles (TCD signal versus temperature) of the catalysts (Ni<sub>1</sub> for A; Ni<sub>2</sub> for C; Ni<sub>3</sub> for E; Ni<sub>1</sub>-Sb for G) and those functionalized with SO<sub>3</sub><sup>2-</sup>/HSO<sub>3</sub><sup>-</sup> (Ni<sub>1</sub>-S for B; Ni<sub>2</sub>-S for D; Ni<sub>3</sub>-S for F; Ni<sub>1</sub>-Sb-S for H). The catalyst surfaces were reduced with H<sub>2</sub> at 50-700 °C with a ramping rate of 10 °C min<sup>-1</sup>. In (A-H), N<sub>H2</sub> values indicate the numbers of H<sub>2</sub> needed to reduce a gram of the catalysts.

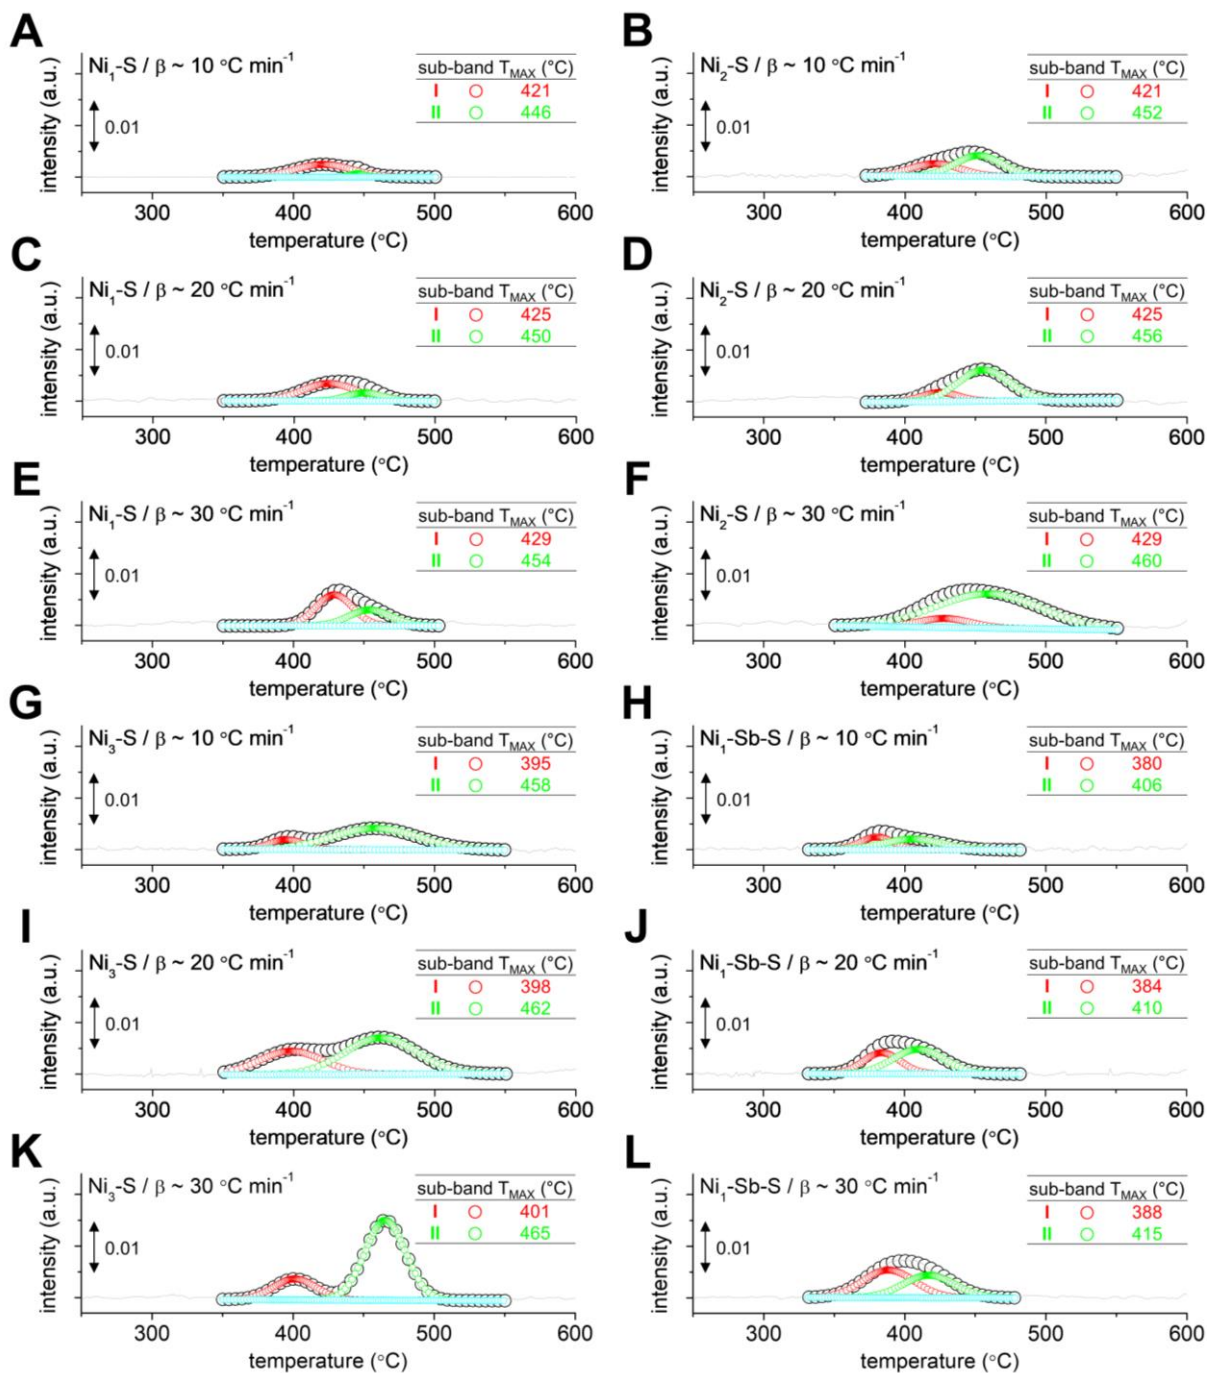

**Fig. S14.** XPS spectra of the catalysts ( $\text{Ni}_1$  for A;  $\text{Ni}_2$  for C;  $\text{Ni}_3$  for E;  $\text{Ni}_1\text{-Sb}$  for G) and those functionalized with  $\text{SO}_4^{2-}/\text{HSO}_4^-$  ( $\text{Ni}_1\text{-S}$  for B;  $\text{Ni}_2\text{-S}$  for D;  $\text{Ni}_3\text{-S}$  for F;  $\text{Ni}_1\text{-Sb-S}$  for H) in the O 1s domains. In (A-F), gray solid lines and black empty circles denote raw and fitted spectra, respectively, whereas purple empty circles indicate backgrounds. In addition, red, green, and blue empty circles denote surface  $\text{O}_\beta$ ,  $\text{O}_\alpha$ , and  $\text{O}'_\alpha$  phases, respectively.

**Fig. S15.** O<sub>2</sub>-pulsed chemisorption profiles of the catalysts (Ni<sub>1</sub> for A; Ni<sub>2</sub> for C; Ni<sub>3</sub> for E; Ni<sub>1</sub>-Sb for G) and those functionalized with SO<sub>4</sub><sup>2-</sup>/HSO<sub>4</sub><sup>-</sup> (Ni<sub>1</sub>-S for B; Ni<sub>2</sub>-S for D; Ni<sub>3</sub>-S for F; Ni<sub>1</sub>-Sb-S for H) at 250 °C. In (A-G), \* corresponds to the onset of TCD signals for O<sub>2</sub>, whose intensities were almost invariant.

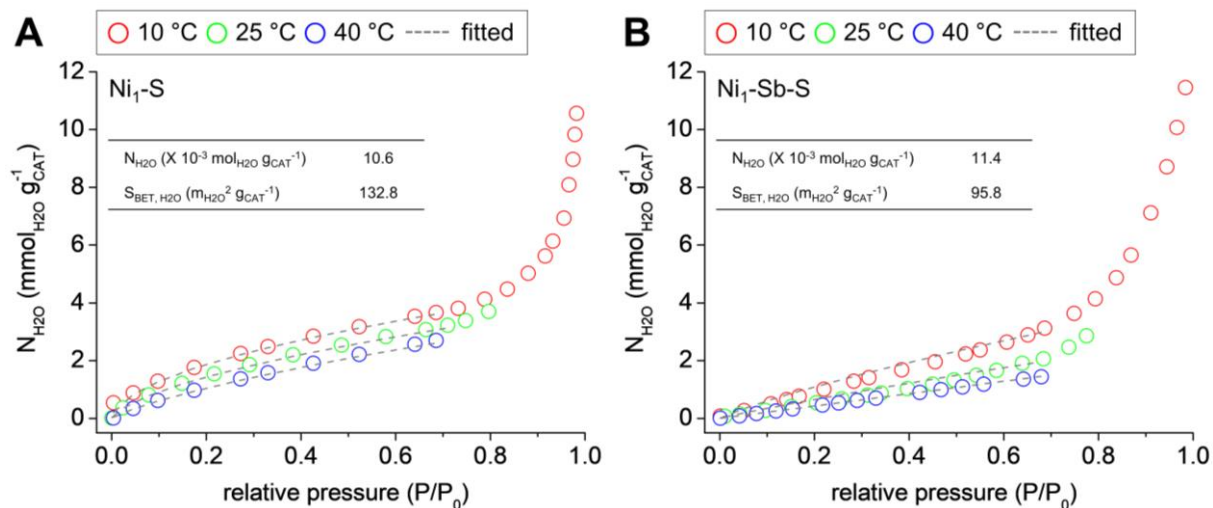

**Fig. S16.** O<sub>2</sub>-TPD profiles (TCD signal versus temperature) of the catalysts functionalized with SO<sub>4</sub><sup>2-</sup>/HSO<sub>4</sub><sup>-</sup> (Ni<sub>1</sub>-S for A, C, and E; Ni<sub>2</sub>-S for B, D, and F; Ni<sub>3</sub>-S for G, I, and K; Ni<sub>1</sub>-Sb-S for H, J, and L). The catalyst surfaces were reduced with H<sub>2</sub> at 300 °C for an hour, cooled to 250 °C, chemisorbed O<sub>2</sub> at 250 °C, and were then heated to 600 °C with a ramping rate ( $\beta$ ) of 10 °C min<sup>-1</sup> (A, B, G, and H), 20 °C min<sup>-1</sup> (C, D, I, and J), or 30 °C min<sup>-1</sup> (E, F, K, and L). In (A-L), O<sub>2</sub>-TPD profiles were de-convoluted using Gaussian function to reveal backgrounds (cyan empty circles) and two sub-bands (I (red empty circle) and II (green empty circle)), whose temperatures with maximum TCD signal intensities ( $T_{MAX}$ ) are presented in inset tables and served to assess O<sub>2</sub> binding energies ( $E_{OL/OM}$ ) of the catalyst surfaces at 250 °C.

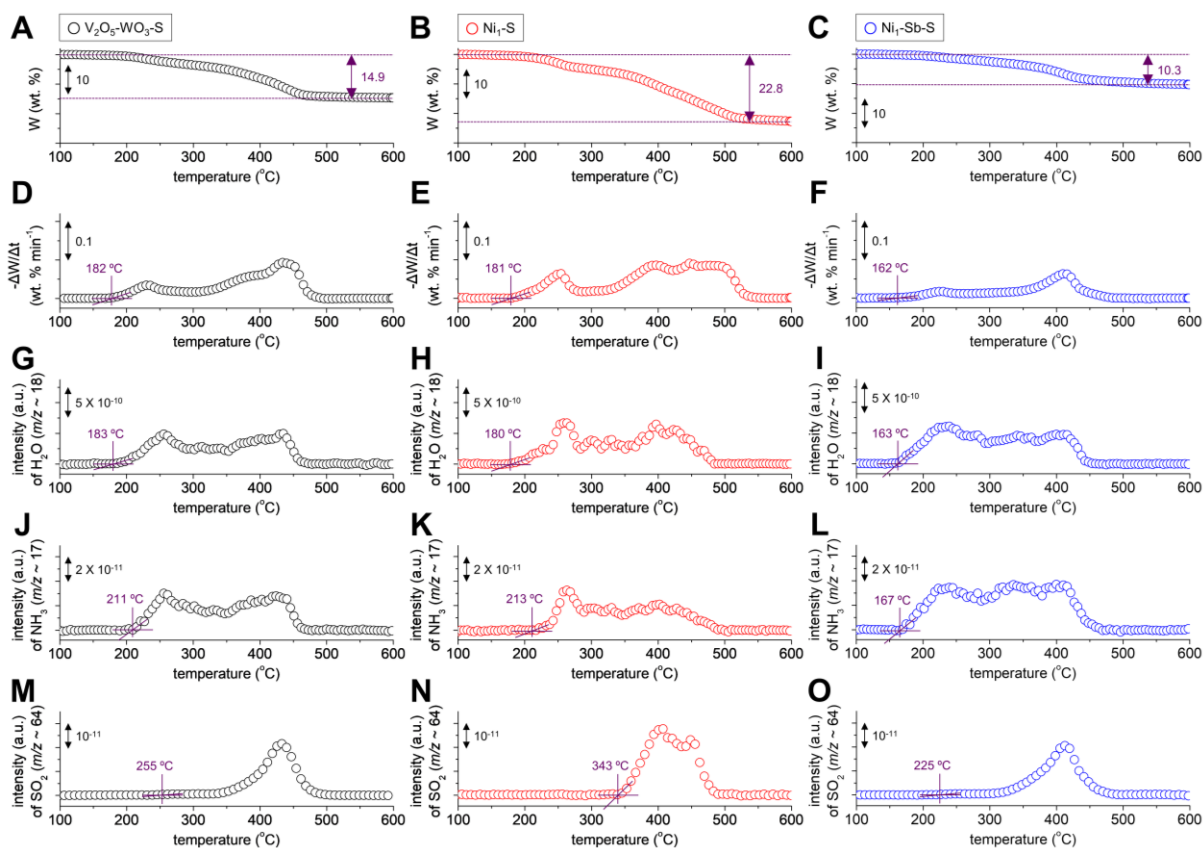

**Fig. S17.**  $\text{SO}_2$ -TPD profiles ( $\text{SO}_2$  concentration ( $C_{\text{SO}_2}$ ) versus temperature) of the catalysts functionalized with  $\text{SO}_4^{2-}/\text{HSO}_4^-$  ( $\text{Ni}_1\text{-S}$  for A;  $\text{Ni}_1\text{-Sb-S}$  for B). The catalyst surfaces chemisorbed  $\text{SO}_2$  at  $220\text{ }^{\circ}\text{C}$  and were then heated to  $900\text{ }^{\circ}\text{C}$  with a ramping rate of  $10\text{ }^{\circ}\text{C min}^{-1}$ . In (A-C),  $N_{\text{SO}_2}$  values indicate the numbers of  $\text{SO}_2$  adsorbed in a per-gram of the catalysts at  $220\text{ }^{\circ}\text{C}$ .

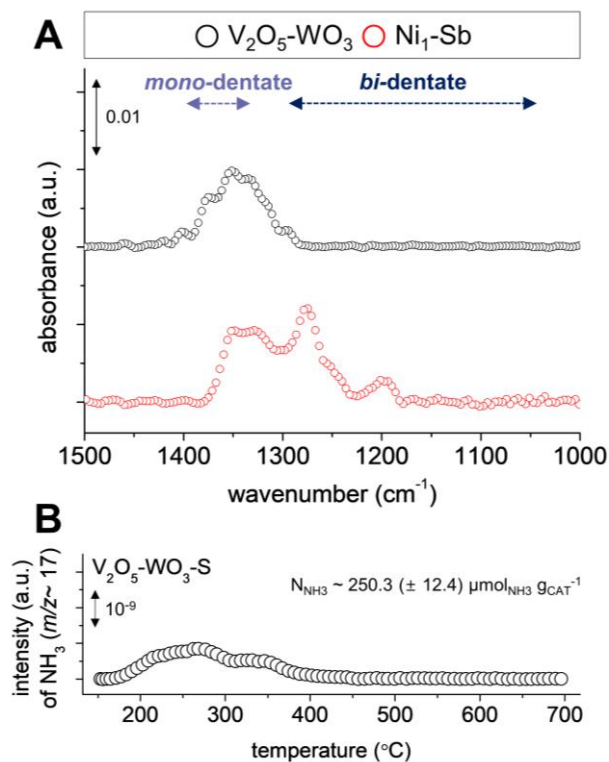

**Fig. S18.** H<sub>2</sub>O adsorption isotherms of Ni<sub>1</sub>-S (A) and Ni<sub>1</sub>-Sb-S (B). In (A-B), red, green, and blue empty circles denote H<sub>2</sub>O adsorption isotherms collected at 10 °C, 25 °C, and 40 °C, respectively, whereas gray dashed lines denote H<sub>2</sub>O adsorption isotherms simulated using Toth equation. In addition, inset tables contain the numbers of H<sub>2</sub>O adsorbed in a per-gram of the catalysts ( $N_{\text{H}_2\text{O}}$ ) at partial pressure ( $P/P_0$ ) of  $\sim 1.0$  and 10 °C alongside with H<sub>2</sub>O-accessible BET surface areas in a per-gram of the catalysts ( $S_{\text{BET, H}_2\text{O}}$ ) at 10 °C.

**Fig. S19.** Profiles of weight percent loss versus temperature (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S for A; Ni<sub>1</sub>-S for B; Ni<sub>1</sub>-Sb-S for C), the 1<sup>st</sup> derivative of weight percent loss with respect to time versus temperature (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S for D; Ni<sub>1</sub>-S for E; Ni<sub>1</sub>-Sb-S for F), and signals of H<sub>2</sub>O (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S for G; Ni<sub>1</sub>-S for H; Ni<sub>1</sub>-Sb-S for I), NH<sub>3</sub> (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S for J; Ni<sub>1</sub>-S for K; Ni<sub>1</sub>-Sb-S for L), and SO<sub>2</sub> (V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>-S for M; Ni<sub>1</sub>-S for N; Ni<sub>1</sub>-Sb-S for O) released versus temperature for the catalysts poisoned with AS/ABS under an Ar. In (A-C), values shown with arrows denote the quantities of AS/ABS (wt. %) included in the poisoned catalysts. In (D-O), temperatures denoted the onsets, where the weight loss or H<sub>2</sub>O/NH<sub>3</sub>/SO<sub>2</sub> signal evolution was initiated. AS/ABS degradation conditions: flow rate of 50 mL min<sup>-1</sup>; ramping rate of 2 °C min<sup>-1</sup>.

**Fig. S20.** (A) Background-subtracted *in situ*  $SO_2/O_2$ -DRIFT spectra of  $V_2O_5-WO_3$  and  $Ni_1-Sb$  exposed to  $SO_2/O_2/N_2$  at  $500\text{ }^{\circ}C$  with a ramping rate of  $10\text{ }^{\circ}C\text{ min}^{-1}$  and a total flow rate of  $200\text{ mL min}^{-1}$ . Background-subtracted *in situ*  $SO_2/O_2$ -DRIFT spectrum of  $Ni_1-Sb$  is re-plotted for comparison. (B)  $NH_3$ -TPD profile ( $NH_3$  signal versus temperature) of  $V_2O_5-WO_3-S$ .  $V_2O_5-WO_3-S$  surface chemisorbed  $NH_3$  at  $150\text{ }^{\circ}C$  and was then heated to  $700\text{ }^{\circ}C$  with a ramping rate of  $10\text{ }^{\circ}C\text{ min}^{-1}$ . In (B),  $N_{NH_3}$  indicates the number of  $NH_3$  adsorbed in a per-gram of  $V_2O_5-WO_3-S$  at  $150\text{ }^{\circ}C$ .
