## 1. Materials and Synthesis

**General.** Unless otherwise indicated, all reactions were carried out under dry and inert conditions by heating all glassware with a heat gun under vacuum and purging with argon. All chemicals and solvents were purchased from commercial suppliers in anhydrous form or were dried by known methods or, in the case of THF were taken from a MBRAUN SPS 800 solvent purification system. Solvents were degassed by the freeze-pump-thaw method. TLC was done using precoated polyester sheets (40×80 mm) from Machery-Nagel (POLYGAM® SIL G/UV254) with 0.2 mm silica gel 60 with fluorescent indicator. A UV light source from Köhler (254 nm and 365 nm, 2·6 W) was used for visualization. NMR spectroscopy was done on Bruker Avance III 400, Bruker Avance III HDX 600, and Bruker Avance III HDX 700 spectrometers. Chemical shifts  $\delta$  are given in ppm, coupling constants  $J$  in hertz (Hz) and standard abbreviations are designated to the multiplicities of the signals. The spectra were calibrated with the solvent residual signals. High resolution mass spectrometry was done with electron spray ionization time of flight mass spectrometry (ESI-TOF-MS) on a maXis 4G Bruker system. UV/Vis absorption spectra were recorded on a PerkinElmer Lambda 1050 spectrometer with a PerkinElmer 3D WB Det Module in 1.0 cm quartz cuvettes, and samples were analyzed in CH<sub>2</sub>Cl<sub>2</sub> at room temperature. Steady-state excitation and emission spectra were recorded on a Horiba Fluorolog-3 DF spectrofluorimeter equipped with a 450 W Xe lamp, and samples were analysed in CH<sub>2</sub>Cl<sub>2</sub> at room temperature. Emission was monitored at a 90° angle using a Hamamatsu R2658P PMT (UV/Vis/NIR, 200 nm <  $\lambda_{\text{em}}$  < 1000 nm) detector. Spectral selection was achieved by the double grating monochromator 320DFX for excitation (1200 grooves/nm, blazed at 330 nm) and the single grating emission monochromator iHR550 for the visible path (1200 grooves/nm, blazed at 500 nm). For the lifetime measurements, a pulsed LED (Horiba DeltaDiode-310,  $\lambda_{\text{em}} = 308 \pm 10$  nm, pulse width ~1 ns FWHM, P<sub>avg</sub> = 5  $\mu$ W) was used. Lifetime data analysis (least square fitting, statistical parameters, etc.) was performed using the software package DAS from Horiba. Lifetimes were determined from the decay curves by an iterative deconvolution fitting method using appropriate multi-exponential functions and taking the instruments response function into account. The instrument used for determination of absolute fluorescence quantum yields was a PerkinElmer FL 8500 Spectrophotometer equipped with a 150 W continuous Xe short arc lamp as excitation source and an integration sphere. Quantum yields were averaged over 4 independent experiments. CPL measurements were carried out with a home-made spectrofluoropolarimeter,<sup>1</sup> mounting a Hamamatsu R-376. The samples concentration was around 2×10<sup>-6</sup> M in dichloromethane. A 365 nm LED was used as the excitation source, employing a 90° geometry. The excitation beam was horizontally polarized. Parameters: slit width = 5 nm, scan speed = 2 nm/sec, integration time = 2 sec, PMT voltage = 550 V, accumulations = 4. The solvent baseline was subtracted from the CPL spectra. ECD spectra were recorded with a Jasco J-1500 spectropolarimeter in dichloromethane solution. The spectra were baseline corrected. All measurements were done in spectroscopy grade solvents.

**Materials.** NBN-Benzo[f,g]tetracene (**3**)<sup>2</sup>, 1-bromo-3,9-dibutyl-NBN-benzo[f,g]tetracene (**5**)<sup>3,4</sup>, (*R*)-/(*S*)-3,3'-diiodo-2,2'-dimethoxy-1,1'-binaphthalene,<sup>5</sup> and (*R*)-/(*S*)-3,3'-diethynyl-2,2'-dimethoxy-1,1'-binaphthalene ((*R*)-/(*S*)-**6**)<sup>6</sup> were prepared according to literature procedures.

## Synthetic Procedures.

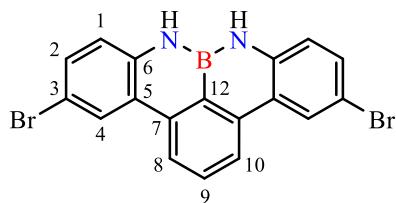

### 3-Bromo-NBN-benzo[*f,g*]tetracene (**4**)

Under ambient conditions, NBN-benzo[*f,g*]tetracene (697 mg, 2.60 mmol, 1.18 eq) is dissolved in acetonitrile (330 ml) and THF (40 ml). The solution is cooled to 0°C and a solution of NBS (393 mg, 2.21 mmol, 1.00 eq) in acetonitrile (20 ml) is added all at once. The cooling bath is not removed, but no additional ice is added so that the solution is allowed to slowly warm to r.t. over night. The mixture is concentrated under reduced pressure, redissolved in ethyl acetate (80 ml), and is transferred to a separation funnel. The organic phase is washed with saturated NaHCO<sub>3</sub> (80 ml), water (80 ml), and brine (50 ml), dried over MgSO<sub>4</sub> and is filtered. Silica is added and the solvent is removed under reduced pressure. The crude product is applied to silica gel chromatography (THF 2/5 hexanes, R<sub>f</sub> = 0.24 in THF 1/2 hexanes) and the product is obtained as a colourless solid (550 mg, 1.59 mmol, 72 %).

### 3,9-Dibromo-NBN-benzo[*f,g*]tetracene

Under ambient conditions, NBN-benzo[*f,g*]tetracene (500 mg, 1.86 mmol, 1.00 eq) is dissolved acetonitrile (270 ml) and THF (35 ml). ## Conformer Analysis with CREST and CENSO

The structures were preoptimized utilizing the semiempirical tight binding GFN-xTB method.<sup>11,12</sup> The obtained geometries were subjected to the conformer-rotamer ensemble sample tool (CREST)<sup>13,14</sup> at the GFN-xTB level of theory with CH<sub>2</sub>Cl<sub>2</sub> as solvent using the XTB<sup>11</sup> program. The conformer ensemble thus obtained was subsequently refined and sorted using the command line energetic sorting (CENSO) program<sup>15</sup> to compute the Boltzmann distribution of populated conformers. The computations were performed with the ORCA 5 software<sup>8–10</sup> and the continuum solvation model (SMD)<sup>16</sup> was applied to simulate solvation in CH<sub>2</sub>Cl<sub>2</sub>.

For the CREST computations standard parameters were applied. The obtained CREST conformers were fed into the CENSO program and part 0, part 1, and part 2 were performed with the following settings:

### Dissymmetry Factor $g_{\text{lum,calcd}}$ .

For detailed information on the procedure to calculate the  $g_{\text{lum}}$  value of compounds we refer to Kubo et al.<sup>17</sup> The geometries of the  $S_1$  states were optimized by analytic gradients<sup>18,19</sup> using TD-DFT along with the def2-SV(P)<sup>12</sup> basis set. The meta-hybrid GGA M06-2X<sup>7</sup> functional was used. The Polarizable Continuum Model (PCM) using the integral equation formalism variant (IEFPCM) was used to simulate an equilibrium solvent reaction field during optimization of the first excited state.<sup>20–23</sup> The TD-DFT calculation from this excited state to the ground state for the transition moments needed for  $g_{\text{lum,calcd}}$  was performed under state-specific equilibrium solvation of the excited state at its equilibrium geometry. Using the corrected linear-response approach, the ground state energy at the excited state geometry was computed under non-equilibrium solvation with the static solvation from the excited state. The difference between the excited state and the ground state energy, both under excited state geometry and solvation correction, gives the vertical emission energy  $E_{\text{ex}}$ . These computations were run with the Gaussian 16 package.<sup>24</sup>

The dissymmetry factor  $g_{\text{lum,calcd}}$  was calculated as follows:  $g = 4R/(D+G)$ . R is the rotatory strength defined by the inner product of transition electric and magnetic dipole moments (it can be either calculated via  $R = |\mu_e| \cdot |\mu_m| \cdot \cos\theta$  or taken from the highlighted R(length) column in Table S1 and Table S2, and D and G are the electric and magnetic dipole strengths defined by the square of transition electric and magnetic dipole moments, respectively ( $D = |\mu_e|^2$ ;  $G = |\mu_m|^2$ ).

**Table S1.** Cartesian coordinates (Å) and transition moments of the optimized structure of (**R**)-**1** in CH<sub>2</sub>Cl<sub>2</sub> in the lowest-energy excited state ( $S_1$ ) calculated at the M06-2X/def2-SV(P) level of theory.
