**Table S4** Chromaticity parameters of the fabricated w-LED as a function of driving current.

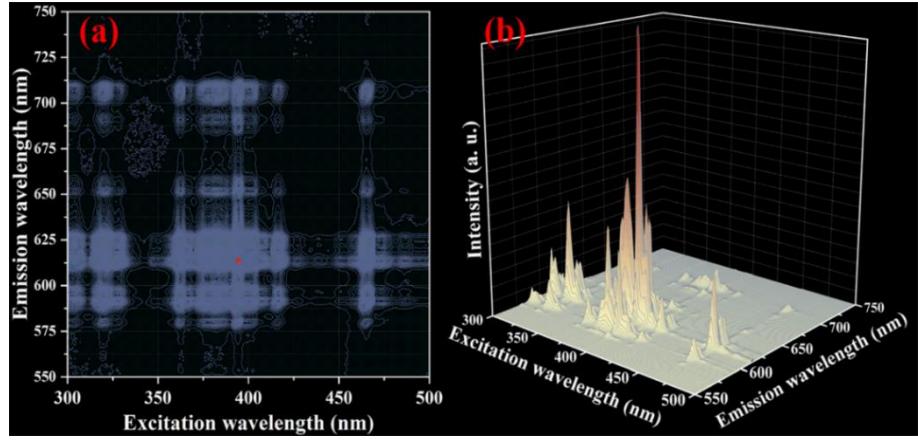

| Current (mA) | Coordinates (x,y) | CCT (K) | $R_a$ |
|--------------|-------------------|---------|-------|
| 20           | (0.3791,0.3810)   | 4068    | 83.0  |
| 40           | (0.3784,0.3794)   | 4075    | 82.7  |
| 60           | (0.3778,0.3791)   | 4090    | 82.8  |
| 80           | (0.3774,0.3783)   | 4094    | 82.9  |
| 100          | (0.3765,0.3770)   | 4111    | 82.6  |
| 140          | (0.3753,0.3754)   | 4133    | 82.7  |
| 180          | (0.3746,0.3739)   | 4145    | 82.2  |
| 220          | (0.3741,0.3723)   | 4145    | 82.0  |
| 260          | (0.3738,0.3705)   | 4142    | 82.0  |
| 300          | (0.3734,0.3674)   | 4132    | 81.4  |

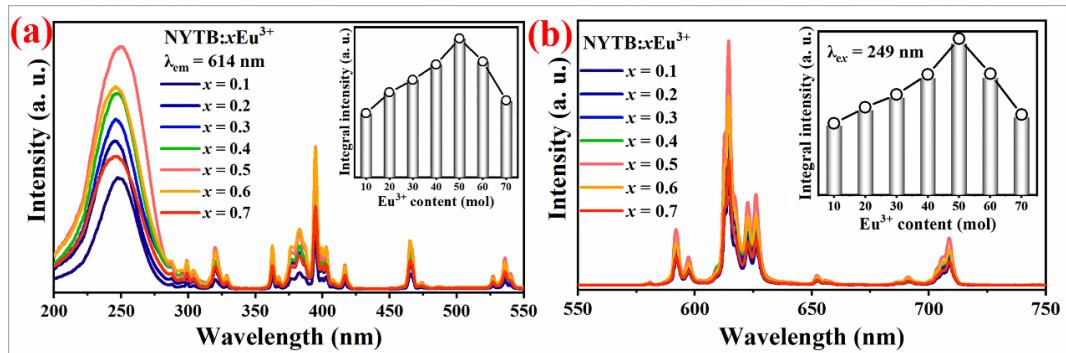

**Fig. S1** XRD patterns of the NYTB host (a) sintered at 780 °C with different times and (b) sintered at different temperatures for 30 min.

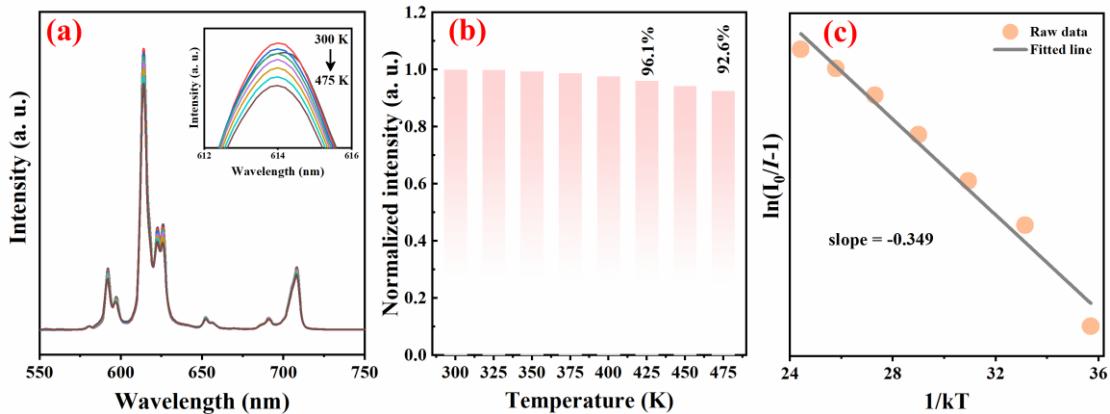

**Fig. S2** Rietveld XRD refinements for NYTB: $x$ Eu<sup>3+</sup> ( $x$  = 0–0.7).

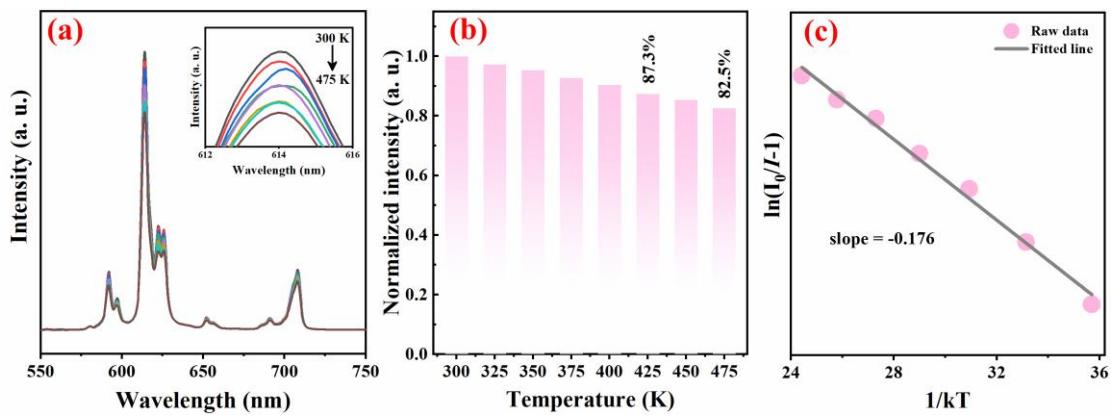

**Fig. S3** (a) Contour line and (b) 3D PL spectra of NYTB:0.5Eu<sup>3+</sup> under various excitation wavelengths.

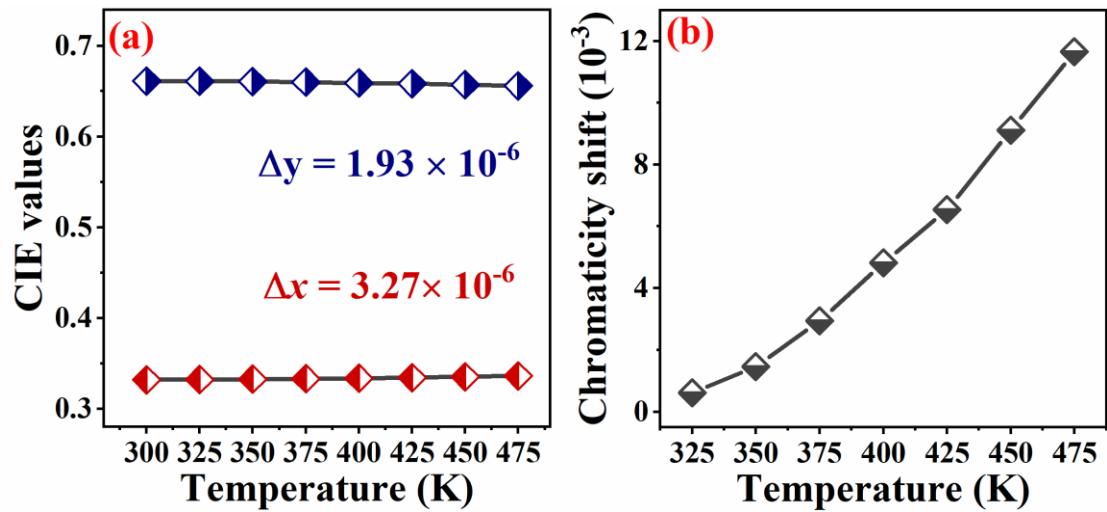

**Fig. S4** (a) PLE spectra and (b) PL emission spectra of NYTB:xEu<sup>3+</sup> (Inset shows integral intensity in response to the Eu<sup>3+</sup> concentration).

**Fig. S5** (a) Temperature-dependent PL of NYTB:0.4Eu<sup>3+</sup>. (b) Normalized intensity as a function of temperature. (c) Plot of  $1/kT$  versus  $\ln(I_0/I-1)$ .

**Fig. S6** (a) Temperature-dependent PL of NYTB:0.6Eu<sup>3+</sup>. (b) Normalized intensity as a function of temperature. (c) Plot of  $1/kT$  versus  $\ln(I_0/I-1)$ .

**Fig. S7** (a) Temperature-dependent CIE (x, y) values and (b) Temperature-dependent chromaticity shift.

### **Formula S1:**

The  $E_g$  values of the NYTB: $x$ Eu $^{3+}$  ( $x = 0$  and  $0.5$ ) samples are estimated by the Tauc relation:<sup>1</sup>

$$[F(R)hv]^{1/n} = A(hv - E_g) \quad (S1)$$

where R, A, and hv represent reflectance, absorption, and photon energy, respectively.

The n values of  $1/2$  and  $2$  correspond to direct and indirect allowed transitions, separately. The NYTB host belongs to an indirect-gap crystal, indicating that the n value is  $2$ .

### **Formula S2:**

Based on Ozawa's theory, the initial quenching concentration is estimated by  $1/(1 + z)$ , in which  $z$  is the number of closest cations around luminescence centers. The emission intensity ( $I$ ) and doping concentration ( $x$ ) can be determined by the following formula:<sup>2</sup>

$$\ln\left(\frac{I}{x}\right) = z\ln(1 - x)C \quad (S2)$$

where C is a constant. The value of  $z$  can be achieved by the slope of  $\ln(I/x)$  vs  $\ln(1-x)$ .

### **Formula S3:**

The critical concentration distance ( $R_c$ ) is estimated by the following expression:<sup>3</sup>

$$R_c = 2\left[\frac{3V}{4\pi x_c Z}\right]^{1/3} \quad (S3)$$

where  $V$ ,  $Z$ , and  $x_c$  represent the unit cell volume, the number of dopant effective sites in the unit cell, and the critical concentration of Eu $^{3+}$  ( $V = 412.576 \text{ \AA}^3$ ,  $Z = 4$ , and  $x_c = 0.5$ ), respectively.

**Formula S4:**

To investigate the EM process between Eu<sup>3+</sup> ions, the Dexter theory is employed:<sup>4</sup>

$$\frac{I}{x} = K[1 + \beta(x)^{\theta/3}]^{-1} \quad (\text{S4})$$

where  $I$  and  $x$  represent the PL intensity and content of Eu<sup>3+</sup> ions, respectively.  $K$  and  $\beta$  are constants. The type of electric multipolar interaction is reflected by the value of  $\theta=6, 8$ , and  $10$ , corresponding to the dipole–dipole, dipole-quadrupole, and quadrupole-quadrupole, respectively.

**Formula S5:**

The external quantum efficiency ( $\eta_0$ ), internal quantum efficiency ( $\eta_i$ ), and absorption factor ( $\alpha_{\text{abs}}$ ) are calculated by the following formula:<sup>5</sup>

$$\eta_0 = \frac{\int L_S}{\int E_R}; \quad \eta_i = \frac{\int L_S}{\int E_R - \int E_S}; \quad \alpha_{\text{abs}} = \frac{\int E_R - \int E_S}{\int E_R} \quad (\text{S5})$$

where  $L_S$  is the PL spectrum of the sample.  $E_R$  and  $E_S$  are the PLE spectra without and with the sample, respectively.

**Formula S6:**

CP can be estimated via the following equation:<sup>6</sup>

$$\text{CP} = \sqrt{(x - x_i)^2 + (y - y_i)^2} / \sqrt{(x_d - x_i)^2 + (y_d - y_i)^2} \quad (\text{S6})$$

where  $x_i$  and  $y_i$  stand for the illuminant point (0.3101, 0.3162), which corresponds to the CIE 1931 Standard Source C. The color coordinates ( $x_d, y_d$ ) come from the dominant emission.

**Formula S7:**

The activation energy ( $E_a$ ) is evaluated by using the following expression:<sup>7</sup>

$$\ln(I_0/I - 1) = \ln A - E_a/kT \quad (\text{S7})$$

where  $I_0$  and  $I$  represent the integral intensities at room temperature and temperature  $T$ , respectively.  $k$  is the Boltzmann constant ( $8.62 \times 10^{-5}$  eV/K), and  $A$  presents a coefficient.

**Formula S8:**

The  $\theta_D$  is evaluated by the following equation:<sup>8</sup>

$$(\theta_D) = \sqrt{\frac{3h^2TN_A}{A_i k U_{iso,i}}} \quad (\text{S8})$$

where  $A_i$  is the atomic weight of the atom,  $h$  is the Planck constant,  $k$  is the Boltzmann constant, and  $U_{iso,i}$  is the average atomic displacement parameter.

**Formula S9:**

The chromaticity shift ( $\Delta E$ ) is used to describe the chromaticity stability. It is calculated by the following formula:<sup>9</sup>

$$\Delta E = \sqrt{(u'_t - u'_0)^2 + (v'_t - v'_0)^2 + (w'_t - w'_0)^2} \quad (\text{S9})$$

where  $u' = 4x/(3 - 2x + 12y)$ ,  $v' = 9y/(3 - 2x + 12y)$ , and  $w' = 1 - u' - v'$ .  
0 and t represent room temperature and given temperature, separately.
