Experimental Section

Chemicals and Reagents

Styrene and pyrrole monomers were purified by filtration through neutral alumina prior to use. Histidine (His), potassium persulfate (KPS), ammonium persulfate (APS), and sodium dodecyl sulfate (SDS) were obtained from Aladdin Chemistry Co., Ltd. Commercial Pt/C (20 wt% Pt) was sourced from Alfa Aesar. Deionized (DI) water (>18.2 M Ω ·cm) was produced using a Millipore Ultrapure water system. All reagents were employed as received without additional purification.

Catalyst preparation

Synthesis Procedures

Preparation of polystyrene (PS) template:

A solution containing anhydrous Na₂CO₃ (0.1 g, 0.94 mmol) and SDS (0.2 g, 0.69 mmol) in 300 mL DI water was stirred under N₂ purge for 30 min. Styrene monomer (30 mL) was injected into the mixture and vigorously stirred at 60°C for 30 min, followed by dropwise addition of KPS aqueous solution (10 mL, 1 mmol). The reaction proceeded at 70°C for 20 h. The resulting PS nanoparticles were centrifuged (12,000 rpm, 30 min), washed repeatedly with DI water, and redispersed in 100 mL DI water to form the PS mother solution.

Fabrication of Co precursors:

PS mother solution (2 mL), Co(NO₃)₂·6H₂O solution (0.5 M, 5 mL), histidine solution (0.5 M, 20 mL), and pyrrole monomer (30 μL) were sequentially added to 50 mL DI water under vigorous stirring. After 10 min, APS solution (0.5 M, 30 mL) was introduced, and the mixture was magnetically stirred for 3 h to deposit polypyrrole (PPy) onto PS surfaces. The product (denoted as PS@Co-His-PPy) was collected via filtration, washed with DI water/ethanol, and dried at 80°C under vacuum for 12 h.

Control samples:

PS@Co-PPy: Synthesized identically but without histidine.

PS@PPy: Prepared by omitting both Co(NO₃)₂ and histidine.

Thermal Conversion to Single-Atom Catalysts:

The precursors (PS@Co-His-PPy and PS@PPy) were pyrolyzed in a tube furnace at 700°C (5°C·min⁻¹, Ar flow) for 2 h. After cooling to room temperature, the resulting materials (Co-SAs/NHC and NHC, respectively) were directly collected for use.

Generalization to other metals: Analogous M-SAs/NHC catalysts (M = V, Cr, Mn, Fe, Ni, Cu, Zn, Bi, Ca, Mg) were synthesized by substituting Co(NO₃)₂·6H₂O with equimolar VOSO₄, Cr(NO₃)₃·9H₂O, MnCl₂, FeSO₄·7H₂O, Ni(NO₃)₂·6H₂O, Cu(NO₃)₂·3H₂O, Zn(NO₃)₂·6H₂O, Bi₂(SO₄)₃, CaCl₂, or MgCl₂.

Characterization

The sizes and morphologies were characterized by a field emission scanning electron microscope (FESEM, Gemini SEM 300) and a transmission electron microscope (TEM, JEOL JEM-F200) with energy dispersive spectroscopy (EDS, JED-2300T). The high resolution and elemental mappings were obtained on a JEOL JEM-2100F at 200 kV Atomic dispersion and imaging were measured by using a TEM (FEI Spectra 300) at 200 keV, equipped with a probe spherical aberration corrector. The crystalline structure and phase purity were recorded on a Powder X-ray diffraction (XRD) (Philips X'pert PRO with nickel-fleered Cu K α radiation (λ = 1.5406 Å)). X-ray photoelectron spectroscopic was used to assess the chemical composition and environment (XPS, Thermo Scientific K-Alpha) using Al K α source (hv = 1486.6 eV). The X-ray absorption spectra (XAS) including X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) of the sample at Co K-edge was collected at the Beamline of TLS07A1 in National Synchrotron Radiation Research Center (NSRRC), Taiwan. Co foil, CoO, and Co₃O₄served as references and were conducted.

XAFS measurements and data analysis details

Data reduction, data analysis, and EXAFS fitting were performed and analyzed with the Athena and Artemis programs of the Demeter data analysis packages that utilizes the FEFF6 program to fit the EXAFS data. The energy calibration of the sample was conducted through a standard Fe foil which as a reference was simultaneously measured. A linear function was subtracted from the pre-edge region, then the edge jump was normalized using Athena software. The $\chi(k)$ data were isolated by subtracting a smooth, three-stage polynomial approximating the absorption background of an isolated atom The K^2 -weighted $\chi(k)$ data were Fourier transformed after applying a Kaiser-Bessel window function ($\Delta k = 1.0$). For EXAFS modeling, the global amplitude EXAFS (CN, R σ^2 and ΔE_0) were obtained by nonlinear fitting, with least-squares refinement, of the EXAFS equation to the Fourier-transformed data in R-space, using Artemis software, EXAFS of the Fe foil is fitted and the obtained amplitude reduction factor S_0^2 value (0.701 was set in the

EXAFS analysis to determine the coordination numbers (CNs) in the Co–O/N scattering path in sample.

Wavelet Transform analysis

For Wavelet Transform analysis, the $\chi(k)$ exported from Athena was imported into the Hama Fortran code. The parameters were listed as follow: R range, 0 - 6.0 Å, k range, 0 - 12.0 Å⁻¹ for Co-SAs/NHC (0-12.0 Å⁻¹ for foil, CoO, Co₃O₄); k weight, 2; and Morlet function with κ =10, σ =1 was used as the mother wavelet to provide the overall distribution.

Zinc-air batteries test

The practical performance of the Co-SAs/NHC catalyst was evaluated using a custom-built electrochemical workstation (OMS-T4, Changsha Spring New Energy Technology Co., China). Galvanostatic charge-discharge cycling experiments were performed using a LAND CT2001A battery analyzer (Wuhan Land Electronic Co., China). For cathode preparation, hydrophobic carbon paper (2 cm × 2 cm) served as the substrate. Uniform deposition of either Co-SAs/NHC ink or commercial Pt/C ink (containing equivalent RuO₂ content) was achieved via spray-coating, maintaining a catalyst deposition density of 1.5 ± 0.1 mg cm⁻². A pristine Zn foil anode was paired with an alkaline electrolyte system containing 6 M KOH and 0.2 M zinc acetate, while a Whatman GF/C glass fiber separator completed the cell configuration.
