## I. Model Hamiltonian Parameters

All values and symmetries of the harmonic ground-state vibrational frequencies  $\omega_i$ , vertical excitation energies  $E^{(n)}$ , on-diagonal linear intrastate coupling constants  $\kappa_i^{(n)}$ , off-diagonal linear inter-state coupling constants  $\lambda_i^{(nm)}$  as well as on-diagonal bilinear (quadratic) coupling constants  $\gamma_i^{(n)}$  as well as the parameters concerning the Morse and quartic potential used in this work are provided in the form of a separate MCTDH operator file. Details on how to read this file can be found in the MCTDH documentation. The most relevant parameters are furthermore listed in Table I, II and III.

TABLE I. Subdivision of all electronic states of the molecular Hamiltonian considered in this work and their corresponding state symmetries and vertical excitation energies  $E^{(\alpha)}$  (in eV) at the Franck-Condon point. A linear vibronic coupling model was used for all sub-Hamiltonians where anharmonicity was taken into account for selected modes and states as noted in the last column. All parameters for  $\mathbf{H}_{v_1}$  were taken from ref.<sup>1</sup>.  $\mathbf{H}_{v_2}$  is described using the parameters from ref.<sup>2</sup> except for a global energy shift of -0.6 eV in order to maintain the energy gap between  $\mathbf{H}_{v_1}$  and  $\mathbf{H}_{v_2}$ .  $\mathbf{H}_{c_1}$  is taken over from ref.<sup>2</sup> without any adjustment while  $\mathbf{H}_{c_2}$  was parameterised within this work.

State	Symmetry	$E^{(\alpha)}$	Anharmonicity
$S_0$	$A_{q}$	0.00	
$S_1$	$B_{3u}$	3.93	
$S_2$	$A_u$	4.45

## II. fs-XANES spectra

Fig. 1 presents simulated differential X-ray absorption spectra disentangled for each individual transition.

FIG. 1. Three-dimensional map displaying computed fs-XANES spectra for each individual transition.

## III. Time Evolution of fs-RIXS spectra

Fig. 2 shows a three-dimensional collection of transient RIXS spectra for an excitation energy of 402.5 eV. Furthermore, a two dimensional representation is illustrated in Fig. 3. The most dominant overlap of the bleach and excited state RIXS signal can be observed between 30 fs and 60 fs. Furthermore, less significant overlap signals can be found at about 110 fs and 175 fs. However, in each case the excited state features are very weak compared to the bleach signal such that a proper extraction of excited state mechanisms are nearly impossible using this excitation energy. The ground state bleach signal contains five dominant emission bands stemming from six core-to-valence state transitions. Its time-independent pattern is explained in the main article.

FIG. 2. Three-dimensional collection of calculated difference RIXS spectra for time delays  $\Delta \tau$  between 5 fs and 200 fs with a step size of 5 fs using an excitation energies of 402.5 eV.

FIG. 3. Time evolution of the difference RIXS spectra between 10 fs and 200 fs with a stepsize of 10 fs steps using an excitation energy of  $\omega_I = 402.5$  fs. Transitions stemming from  $X_1$ ,  $X_2$ ,  $X_3$  and  $X_4$  are highlighted in red, blue, green and yellow, respectively. The elastic peak at 0 eV is downscaled to 25% for a better visualisation.

A two dimensional representation of the time evolution of the transient RIXS spectra computed with excitation energies of 399.0 eV and 401.5 eV are given in Fig. 4 and Fig. 5, respectively. Their behaviour is discussed in the main article.

FIG. 4. Time evolution of the RIXS spectra between 10 fs and 200 fs with a stepsize of 10 fs steps using an excitation energy of  $\omega_I = 399.0$  fs. Transitions stemming from  $X_1$  and  $X_2$  are highlighted in red and blue, respectively.

FIG. 5. Time evolution of the RIXS spectra between 10 fs and 200 fs with a stepsize of 10 fs steps using an excitation energy of  $\omega_I = 401.5$  fs. Transitions stemming from  $X_3$  and  $X_4$  are highlighted in green and yellow, respectively.
