## Part 1: METHODS

### Part 1.1 Model preparation and set-up

Initially, we took the guaethol-bound CYP255A and *p*-anisic acid-bound CYP199A4 structures from the Protein Data Bank (PDB, see Fig. S1),<sup>1</sup> where they are deposited under the PDB codes 5OMS<sup>2</sup> and 4DO1,<sup>3</sup> respectively. We added hydrogen atoms to each structure using the H++ webserver considering pH 7 conditions.<sup>4</sup> All protonation states of titratable residues were further manually inspected, and all carboxylate groups were in their deprotonated forms, while all Arg and Lys side chains were protonated. All His amino acid side chains were singly protonated on either the N<sub>δ</sub> or N<sub>ε</sub> atom. Thereafter, each system was manually converted into a Compound I (CpdI) structure by adding an oxygen atom to the heme at a distance of 1.686 Å above the iron atom, such that its four surrounding nitrogen atoms and this newly added oxygen atom created a pyramidal geometry.

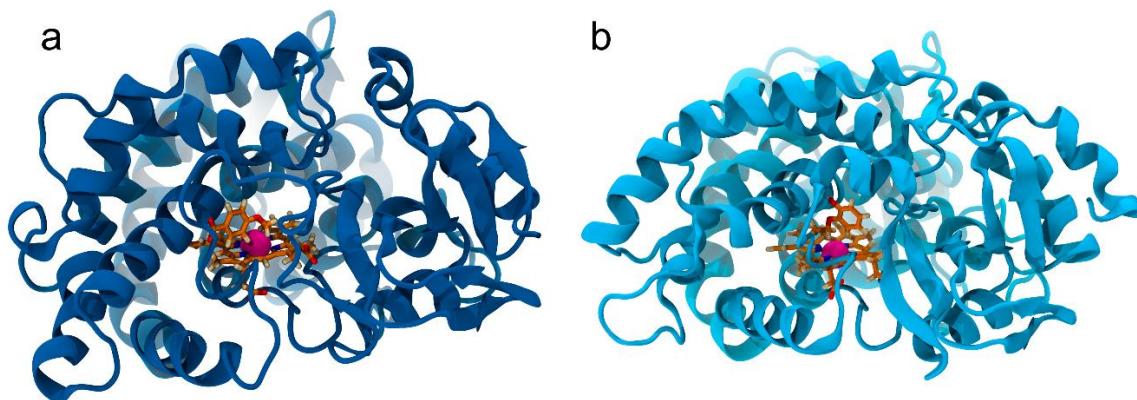

Fig. S1. P450 enzymes studied in this work: a) CYP199A4 bound to *p*-anisic acid; b) CYP255A bound to guaethol.

Prior to the molecular dynamics (MD) simulations, we applied the MCPB.py<sup>5</sup> routine available in Amber 2018<sup>6</sup> to generate force field parameters needed to simulate each heme complex. This set-up calculation took into consideration the first-coordination sphere ligands, that is, the porphyrin ring, the newly added distal oxo group, and the axial ligand whose sulfur atom belongs to a cysteine residue from the L-helix in each system. Once such parameters were generated, we used the LEaP module as available in Amber 2018 to solvate each structure with TIP3P water in separate rectangular boxes with 10 Å of padding in all directions and sodium and chloride ions to render a simulation box with net charge zero.<sup>7</sup>

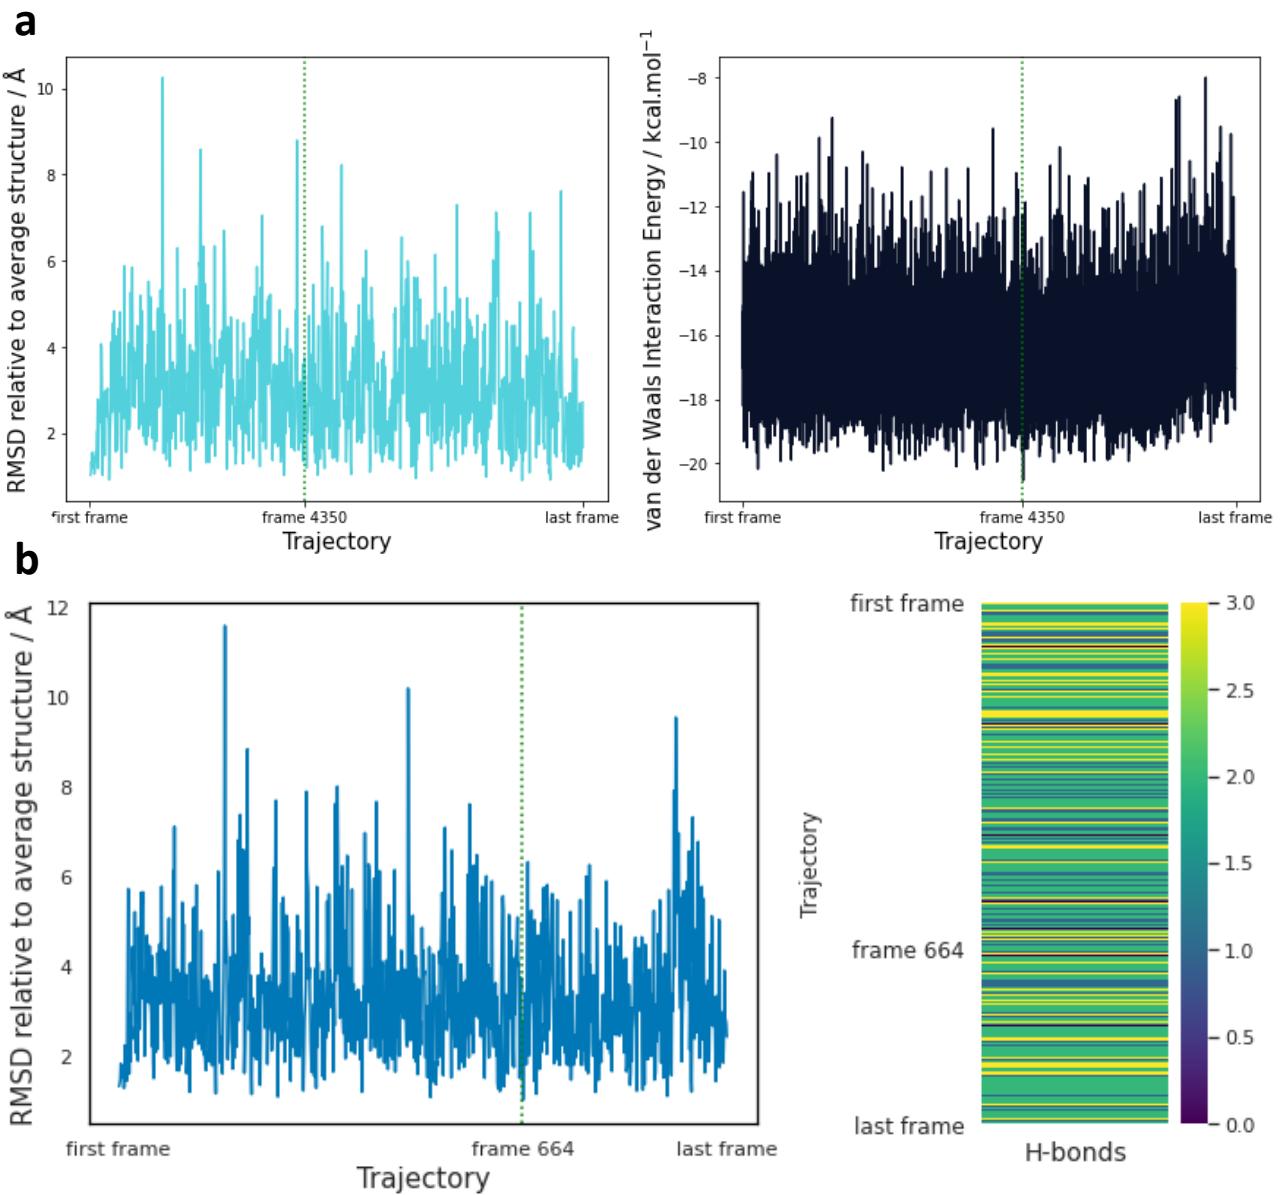

## Part 1.2 Molecular dynamics approaches

The protein and substrate (guaethol for CYP255A and 4-methoxybenzoate for CYP199A4) atoms were described by the ff14SB<sup>8</sup> force field and each system was subjected to 10,000 steps of energy minimization, that is 5,000 of steepest descent followed by 5,000 of conjugate gradient. The energy-minimized structures were then heated and equilibrated in three consecutive steps at constant pressure for 40 picoseconds, in steps of 2 femtoseconds, each:

- i. Heating from 0 to 150 K with harmonic restraints of 10 kcal mol<sup>-1</sup> Å<sup>-2</sup> on all alpha-carbons as well as on heme, iron, distal oxo and substrate atoms.
- ii. Heating from 150 to 300 K with harmonic restraints of 5 kcal mol<sup>-1</sup> Å<sup>-2</sup> on all alpha-carbons as well as on heme, iron, distal oxo and substrate atoms.
- iii. Equilibration at 300 K with harmonic restraints of 5 kcal mol<sup>-1</sup> Å<sup>-2</sup> only on heme, iron, distal oxo and substrate atoms.

The production runs lasted 100 ns and were free of restrictions at 300 K and 1 atm. For each system's run, we took into consideration two factors for picking out the configuration to move forward with QM calculations (Fig. S2):

- i. Frames with strong and stabilizing non-bonded forces between substrate and active site residues (number of hydrogen bonds in CYP199A4 and strength of van der Waals interactions, since they have strongly polar and non-polar active sites, respectively).
- ii. Frames whose active site residues configuration was the closest possible to the average structure throughout the entire run, RMSD-wise – this way we could sort out potential reactive configurations from the MD trajectories.

*Fig. S2. Frame selection from the MD trajectories: a) For CYP255A, the production run frame 4350 was structurally similar to the average structure throughout the entire simulation and had the most stabilizing van der Waals interaction energy between substrate and active site residues, thus this frame was picked for the next DFT calculations; b) wildtype CYP199A4 production run frame 664 was structurally similar to the average structure throughout the entire simulation and had the maximum number of hydrogen bonds (3) between substrate and active site residues, therefore it was picked for the next DFT calculations.*

### Part 1.3 QM cluster model set-up

Once the most representative frame from each trajectory was selected, an active site cluster model was created using previous approaches.<sup>9,10</sup> To do so, we selected the amino acid residues that make up the active site in each system and trimmed out all other atoms. Thus, CYP199A4 cluster model was composed by 255 atoms (Fig. S3a), namely including a truncated porphyrin ring with all side chains replaced by hydrogen atoms, the iron atom with its distal oxo and axial thiolate ligands, the *p*-anisic acid molecule, three water molecules, and the atoms of residues Ser<sub>244</sub>, Arg<sub>243</sub>, Arg<sub>92</sub>, Ser<sub>247</sub>, Ala<sub>248</sub>, Gly<sub>249</sub>, Phe<sub>182</sub>, Val<sub>183</sub>, Phe<sub>298</sub>, Phe<sub>185</sub>, Thr<sub>252</sub>, Glu<sub>99</sub>, Leu<sub>98</sub> and Ser<sub>95</sub> – and CYP255A cluster model was composed of 306 atoms (Fig. S3b) – the truncated porphyrin ring, the iron atom with its distal oxo and axial –SCH<sub>3</sub> ligands, the guaethol molecule, two water molecules, the side chain of residues Cys<sub>356</sub>, Val<sub>241</sub>, Tyr<sub>242</sub>, Ile<sub>80</sub>, Ile<sub>81</sub>, Leu<sub>244</sub>, Phe<sub>395</sub>, Gly<sub>245</sub>, Ala<sub>246</sub>, Asn<sub>248</sub>, Glu<sub>249</sub>, Ile<sub>292</sub>, Phe<sub>75</sub>, Phe<sub>169</sub>, Ala<sub>295</sub>, Thr<sub>296</sub> as well as the backbone atoms of residues Leu<sub>243</sub> and Met<sub>247</sub>. Protein residues were truncated by replacing the aliphatic C–C bond that is broken by C–H a capping atom. The net charge of the CYP255A QM-model was –1, whereas that of CYP199A4 was zero.

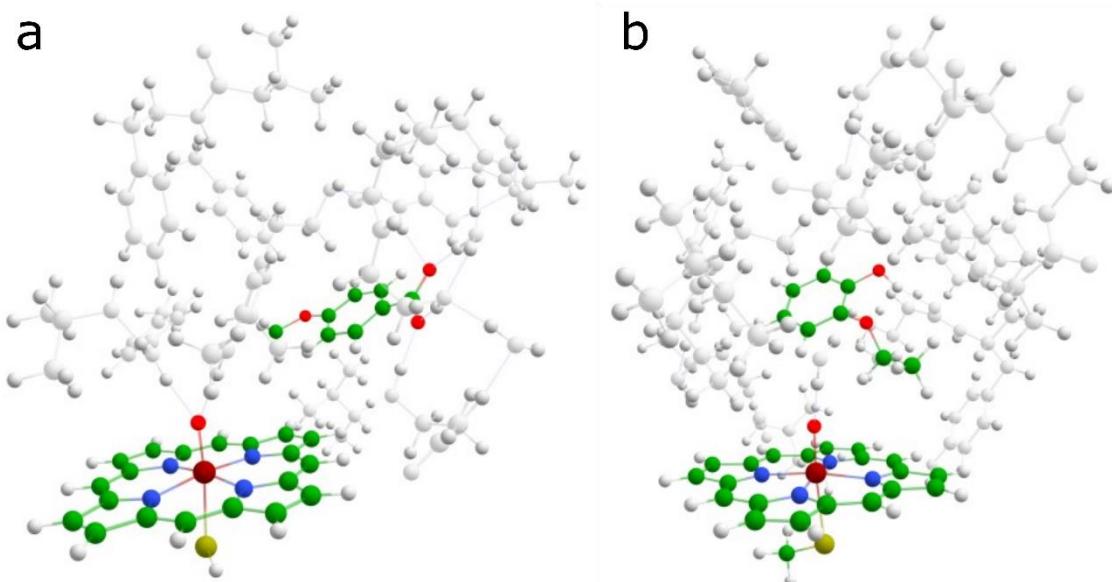

Fig. S3. QM Cluster Models investigated in this study, with protein and water residues coloured in white for clarity: a) CYP 199A4 reduced to its catalytic centre in 255 atoms; b) CYP255A active site assembled in 306 atoms.

For each individual system, we then carried out DFT calculations using the Gaussian-09 software package.<sup>11</sup> All structures – reactants, intermediates, products, and transition states – were optimized without constraints in the gas phase. Two spin states were taken into consideration for the reaction mechanisms studies, namely doublet ( $S = 1/2$ ) and quartet ( $S = 3/2$ ), which are henceforth identified by superscripts 2 and 4 in front of the label, respectively. The calculations were carried out using the unrestricted hybrid density functional UB3LYP with a split-valence basis set described with the LanL2DZ basis set with effective core potential on iron, and for the C, H, N, O, and S atoms the 6-31G\* basis set was employed (basis set BS1).<sup>12,13</sup> Potential energy scans were performed along various reaction coordinates to establish possible mechanisms and to obtain starting structures for the transition state searches along a particular degree of freedom. Full geometry optimizations for the transition state structures were performed and their outcome was confirmed by a frequency calculation. A single imaginary frequency involving the correct vibrational distortion confirmed the structure to be a transition state, while local minima were confirmed by finding real frequencies only.

To describe the energy landscape more accurately, we performed single-point calculations with a continuum polarized conductor model with a dielectric constant mimicking chlorobenzene, which is a good mimic for the active site of P450 systems ( $\epsilon = 4.7$ ),<sup>14</sup> and 6-311+G\* basis set on H, C, N, O, and S atoms and LACV3P+ basis set with core potential on iron (basis set BS2).

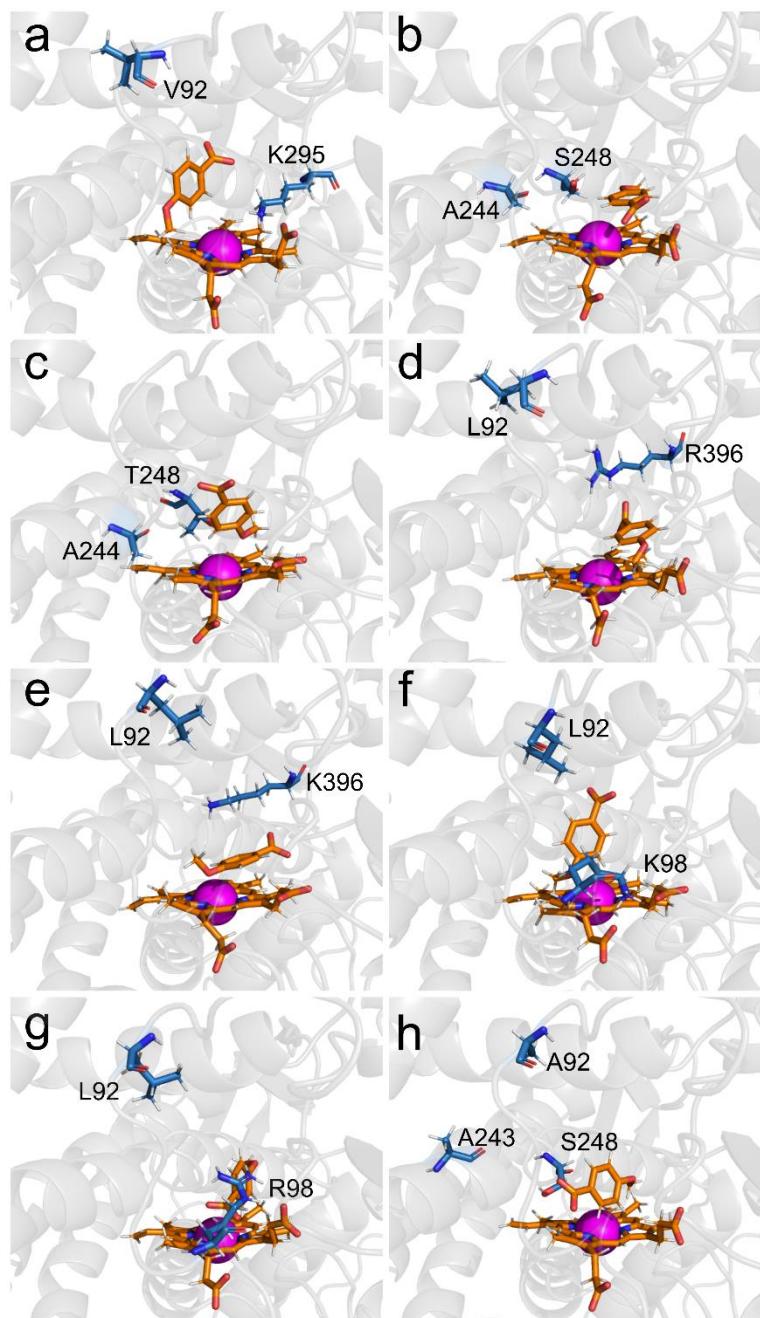

## Part 1.4 Mutant structures set-up

We created a set of mutants of CYP199A4 based on visual inspection of the crystal structure 4DO1, whereby the substrate-binding position and orientation was changed so that its reactivity would lead to changes in product distributions. This was tested, for instance, by moving the position of the active site Arg residue (Arg<sub>92</sub> in wildtype) as it is known to form a salt-bridge with the carboxylate group of the substrate. Further substrate position and orientation in the active site is achieved through hydrophobic interactions with aliphatic amino acid residues in the active site. The complete set of mutants and their respective mutations tested is as shown in Table S1.

**Table S1. CYP199A4 mutations investigated in this work.**

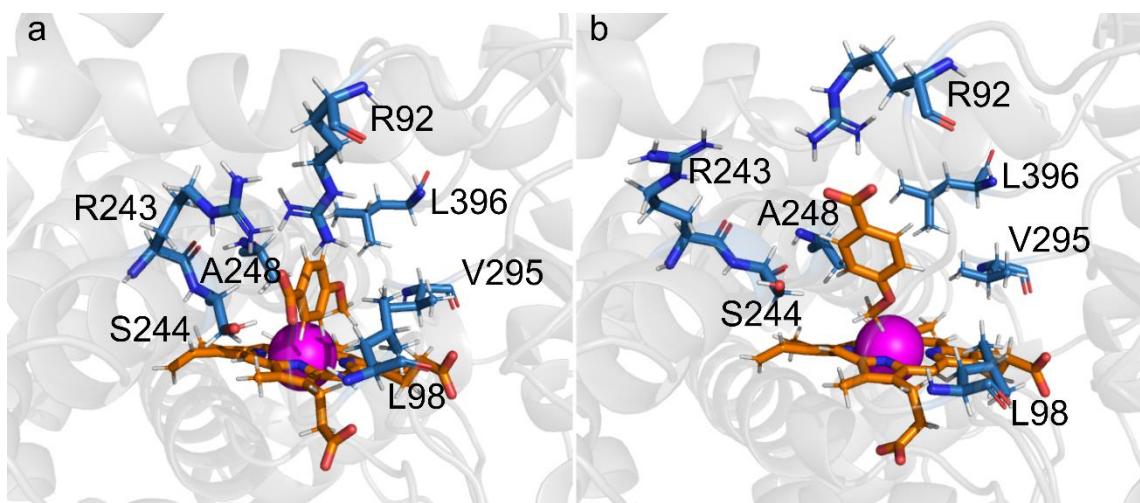

Mutant	Mutations
A	Arg92Val / Val295Lys
B	Ser244Ala / Ala248Ser
C	Ser244Ala / Ala248Thr
D	Arg92Leu / Leu396Arg
E	Arg92Leu / Leu396Lys
F	Arg92Leu / Leu98Lys
G	Arg92Leu / Leu98Arg
H	Arg92Ala / Arg243Ala / Ala248Ser

Each mutant was generated using VMD software package,<sup>15</sup> and followed by steps of energy minimization and equilibration with explicit solvent in the same fashion as described above for the wildtype structures. Subsequently, *p*-anisic acid was inserted into the protein structures using molecular docking procedures as carried out with the AutoDock Vina software package<sup>16</sup> using an approximately cubic search box of volume 1.363 nm<sup>3</sup> centered exactly on the distal oxo ligand of CpdI. The maximum energy difference between the best binding mode and the worst one was set to 2 kcal mol<sup>-1</sup>, the exhaustiveness of the search engine was set to maximum, and the maximum number of binding modes was set to 10.

*Fig. S4. Mutant CYP199A4 structures, after energy minimization, heating, and substrate docking but prior to MD simulations: a-h) mutants A-H (see Table S1).*

The lowest-energy binding pose for each mutant was then solvated following the same procedures described above. Each CYP<sup>MUTANT</sup>-substrate<sup>DOCKED</sup> complex (Fig. S4) was subjected to energy minimization, heating, equilibration, and a production run following the same parameters aforementioned for the wildtype complex. In this case, each CYP<sup>MUTANT</sup>-substrate<sup>DOCKED</sup> production run lasted 1  $\mu$ s. Additionally, wildtype CYP199A4 had an additional 100 ns-run with the substrate positioned in an alternative configuration, which was obtained by re-docking *p*-anisic acid into the active site of CYP199A4 through the same procedure described above (Fig. S5).

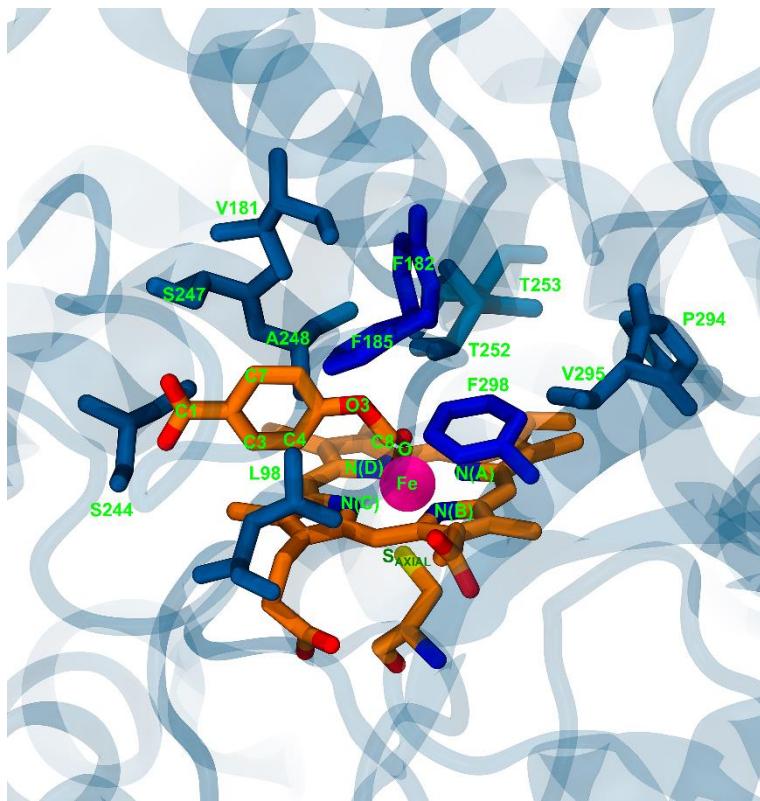

*Fig. S5.* Starting structures for the two wildtype CYP199A4 molecular dynamics runs: a) 4-methoxybenzoate positioned on the active site as it is found in the 4DO1 PDB entry; b) *p*-anisic acid docked onto the active site following the best solution proposed by AutoDock Vina.

## Part 1.5 Machine-learning aided mutant selection

In order to find mutants with different regioselectivity of reaction with *p*-anisic acid, we applied an unsupervised machine learning strategy, which was carried out as follows: Firstly, we divided each CYP<sup>MUTANT</sup>-substrate<sup>DOCKED</sup> production run into 10 bins of 100 ns each. We analyzed each trajectory bin, including the two wildtype 100 ns bins in terms of 13 geometrical and force field-related collective variables (Fig. S6 and Parts 2.2 and 2.3):

1. The distance between O<sub>CpdI</sub> and C8<sub>SUBSTRATE</sub>;
2. The distance between O<sub>CpdI</sub> and C3<sub>SUBSTRATE</sub>;
3. The distance between O<sub>CpdI</sub> and C7<sub>SUBSTRATE</sub>;
4. The distance between N(A)<sub>HEME</sub> and C8<sub>SUBSTRATE</sub>;
5. The distance between N(B)<sub>HEME</sub> and C8<sub>SUBSTRATE</sub>;
6. The distance between N(C)<sub>HEME</sub> and C8<sub>SUBSTRATE</sub>;
7. The distance between N(D)<sub>HEME</sub> and C8<sub>SUBSTRATE</sub>;
8. The RMSD<sub>SUBSTRATE</sub> relative to its average structure throughout the run;
9. The van der Waals interaction energy between substrate and the main phenylalanine residues of the active site – Phe<sub>182</sub>, Phe<sub>185</sub> and Phe<sub>298</sub>;
10. The electrostatic interaction energy between substrate and all protein residues within 8 Å of O<sub>CpdI</sub>;
11. The active site fluctuation, measured as the RMSF of all protein residues within 8 Å of O<sub>CpdI</sub>;
12. The angle Fe-O3<sub>SUBSTRATE</sub>-C1<sub>SUBSTRATE</sub>;
13. The dihedral S<sub>AXIAL</sub>-Fe-O<sub>CpdI</sub>-C4<sub>SUBSTRATE</sub>.

*Fig. S6.* The active site structure of CYP199A4 highlighting all atoms and residues that make up the collective variables that describe the behaviour of our systems throughout the molecular dynamics simulations.

Sequentially, all collective variables were normalized and assembled into a dataset. Principal Component Analysis (PCA) was applied to decorrelate the variables in this initial dataset, and a new one was created with only the principal components that captured the most relevant share of information from the original dataset<sup>17</sup> (see figure S29).

Next, we assessed the best way to clusterize our new dataset, by means of the following clustering metrics: *i*) inertia; *ii*) Calinski-Harabasz index; *iii*) silhouette coefficient; *iv*) Davies-Bouldin index. Firstly, inertia measures how compact the clusters are, this metric is calculated as the sum of squared distances between each datapoint and its nearest cluster centre – the best value is assessed by the elbow method, which indicates the number of clusters at which this metric starts to level off.<sup>18</sup> Secondly, Calinski-Harabasz index evaluates the ratio of between-cluster dispersion and within-cluster dispersion. It is calculated as the ratio of the sum of between-cluster dispersion and within-cluster dispersion – higher values indicate better-defined clusters.<sup>19</sup> Thirdly, the silhouette coefficient measures how similar a datapoint is to its own cluster compared to other clusters, and it ranges from -1 to 1 – a high silhouette score indicates that the datapoint is well matched to its own cluster and poorly matched to neighbouring clusters.<sup>20</sup> Lastly, the Davies-Bouldin index measures the average similarity between each cluster and its most similar cluster, taking into account both the within-cluster

and between-cluster distances – lower values indicate better clustering, and a value of 0 indicates perfect clustering.<sup>21</sup>

Having reached convergence on the optimal number,  $n$ , of clusters for our datapoints (see figure S30), we applied the  $K$ -Means algorithm as implemented in Scikit-learn package,<sup>22</sup> setting its hyperparameter “number of clusters” equal to  $n$ . The t-Distributed Stochastic Neighbour Embedding (tSNE)<sup>23</sup> was used to bring the multi-dimensional data into a bidimensional plot. The best mutant was selected according to the Jaccard Similarity<sup>24</sup>: This score was calculated for each CYP199A4 variant (WT and mutants) pair, following the rational that, if two variations are grouped in the same cluster, they behave similarly, and thus lead to a similar product distribution. Therefore, we searched for the mutant whose datapoints were not clustered with any wildtype datapoint.

Finally, the selected mutant was subjected to DFT calculations using a QM cluster model and calculations were performed as described above for aromatic hydroxylation and  $O$ -demethylation of the substrate. To do so, we selected the best frame from the molecular dynamics trajectory, trimmed it to create a QM-cluster model, and ran full DFT calculations with it, all following the same criteria as stated above for the wildtype CYPs.

## Part 1.6 Evolutionary Scale Modelling on Mutants

We then applied the Evolutionary Scale Model (ESM) approach on wildtype and mutant structures to understand their structural similarities.

---

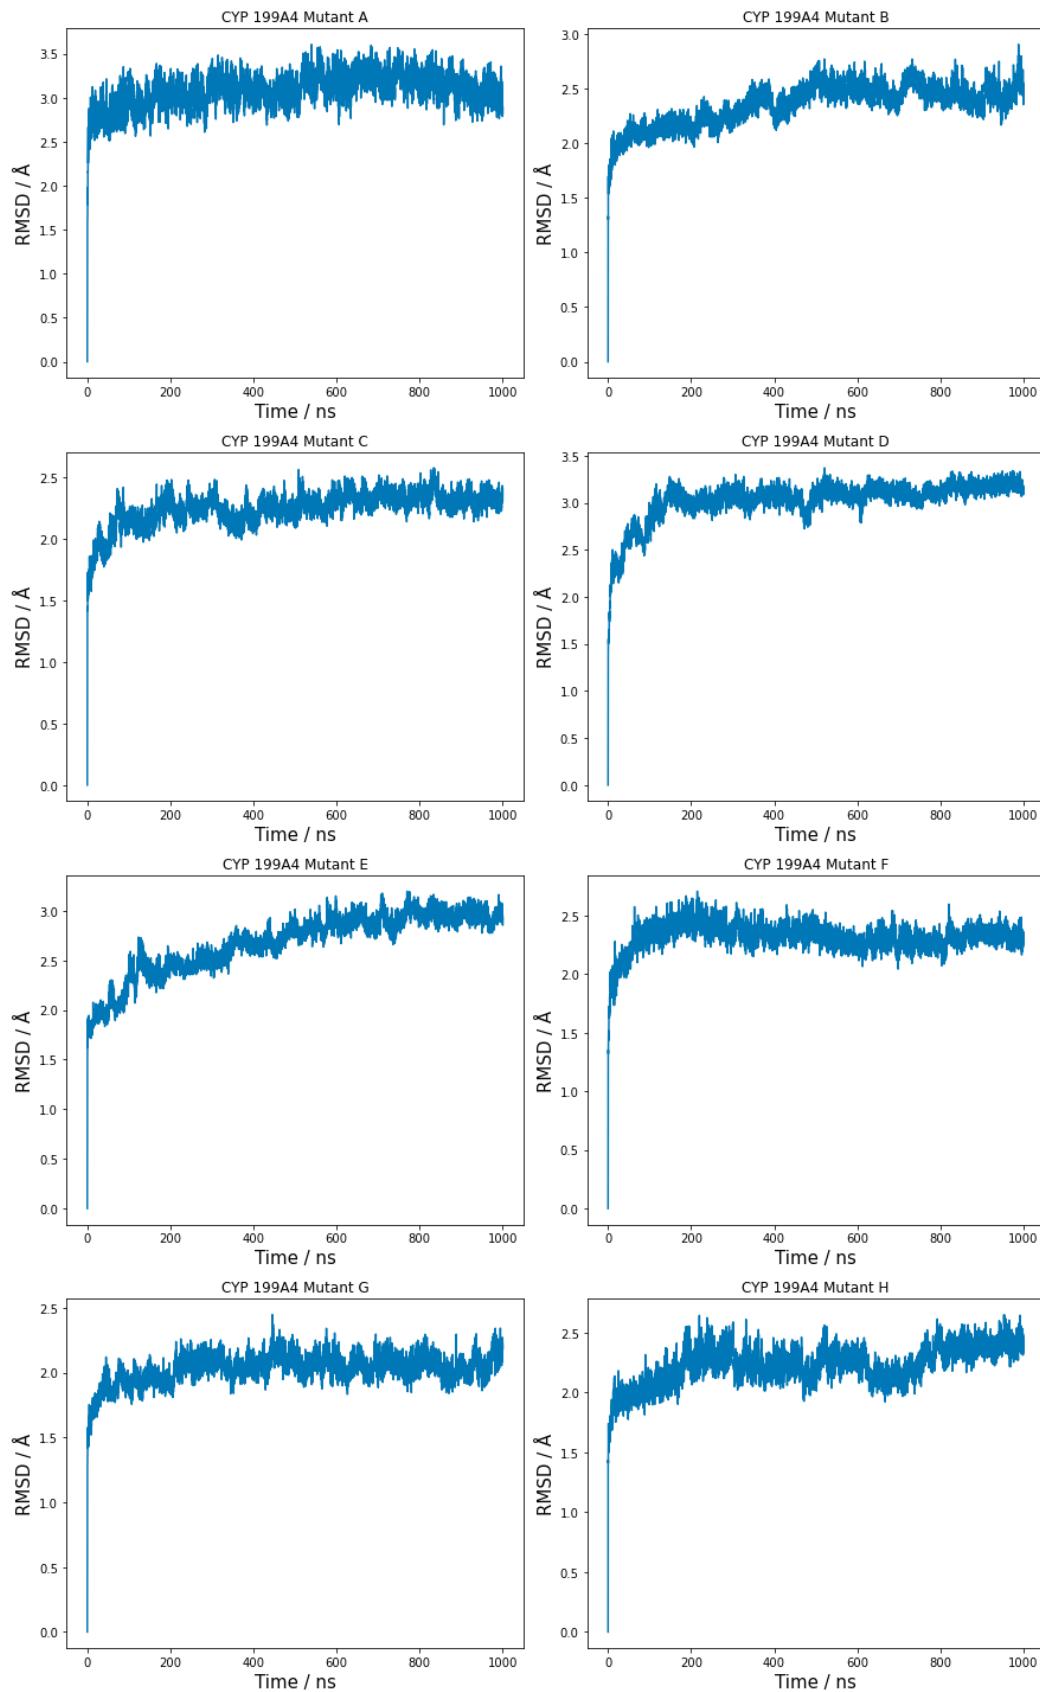

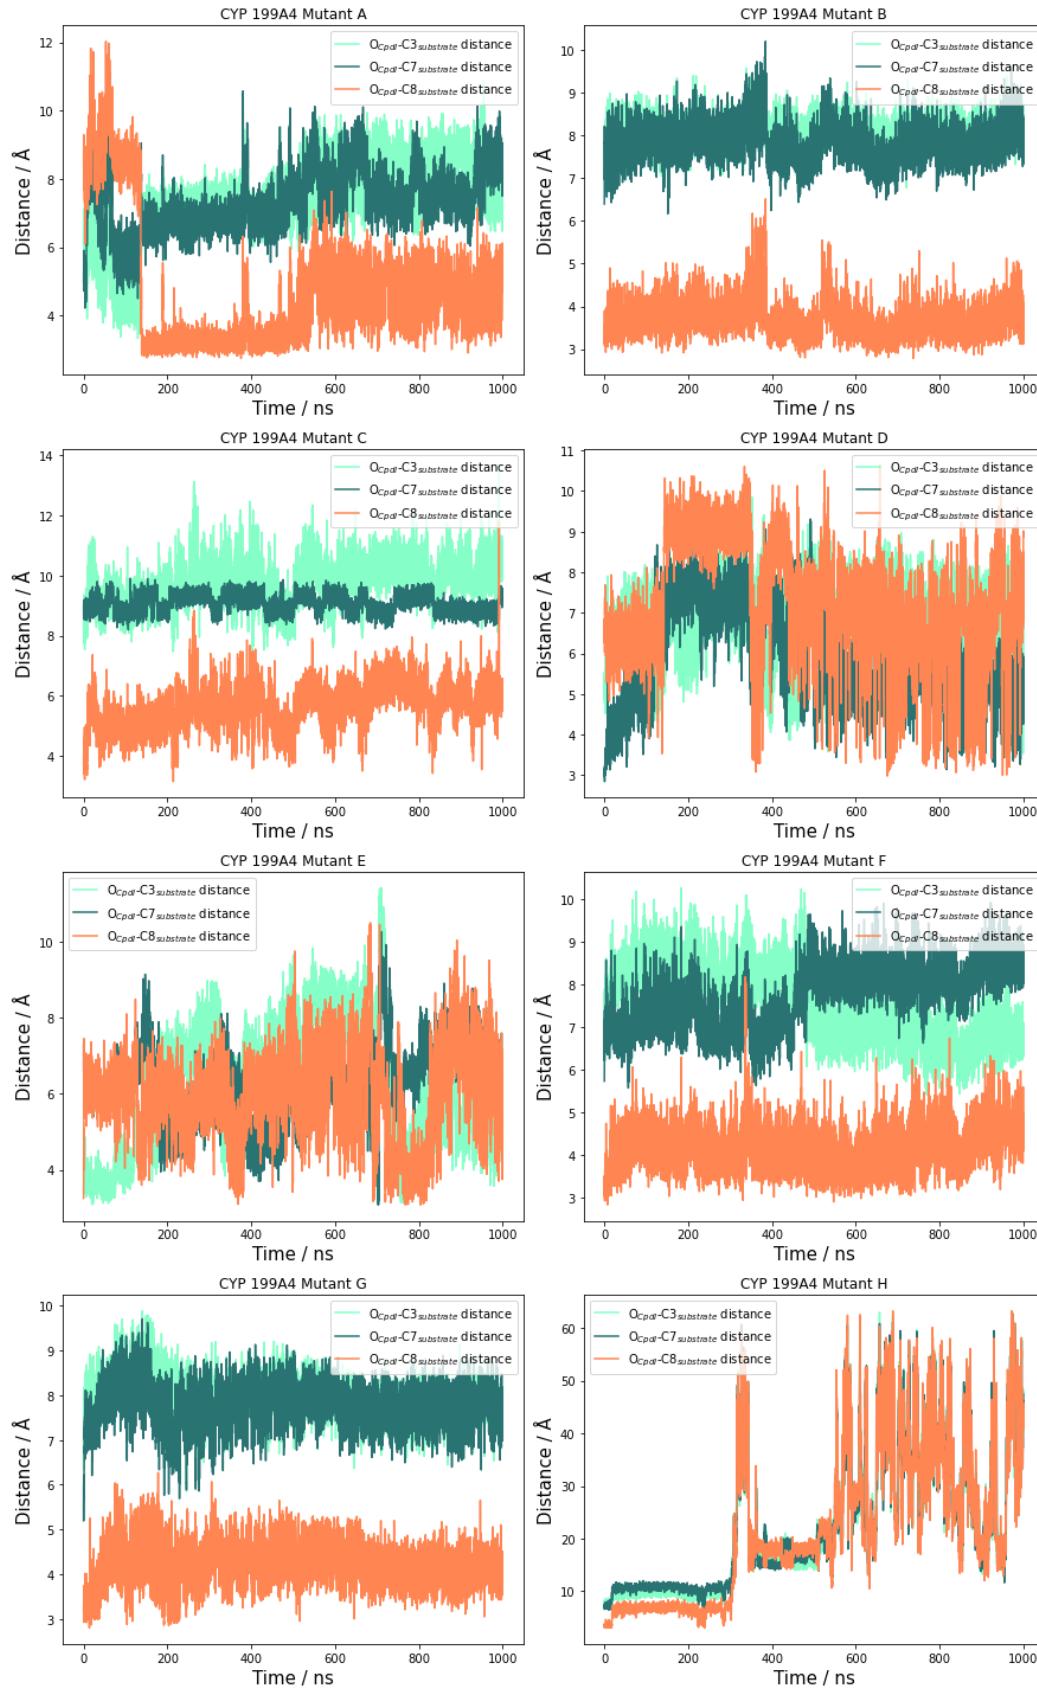

Fig. S21. All-atoms RMSD of mutant CYP199A4 structures (protein+heme) throughout 1  $\mu$ s of MD production run. Top-Down and Left-Right: mutants A-H.

*Fig. S22. Euclidean distance between  $O_{CpdI}$  and atoms C3, C7, and C8 of substrate in mutant CYP199A4 systems throughout 1  $\mu$ s of MD production run. Top-Down and Left-Right: mutants A-H.*

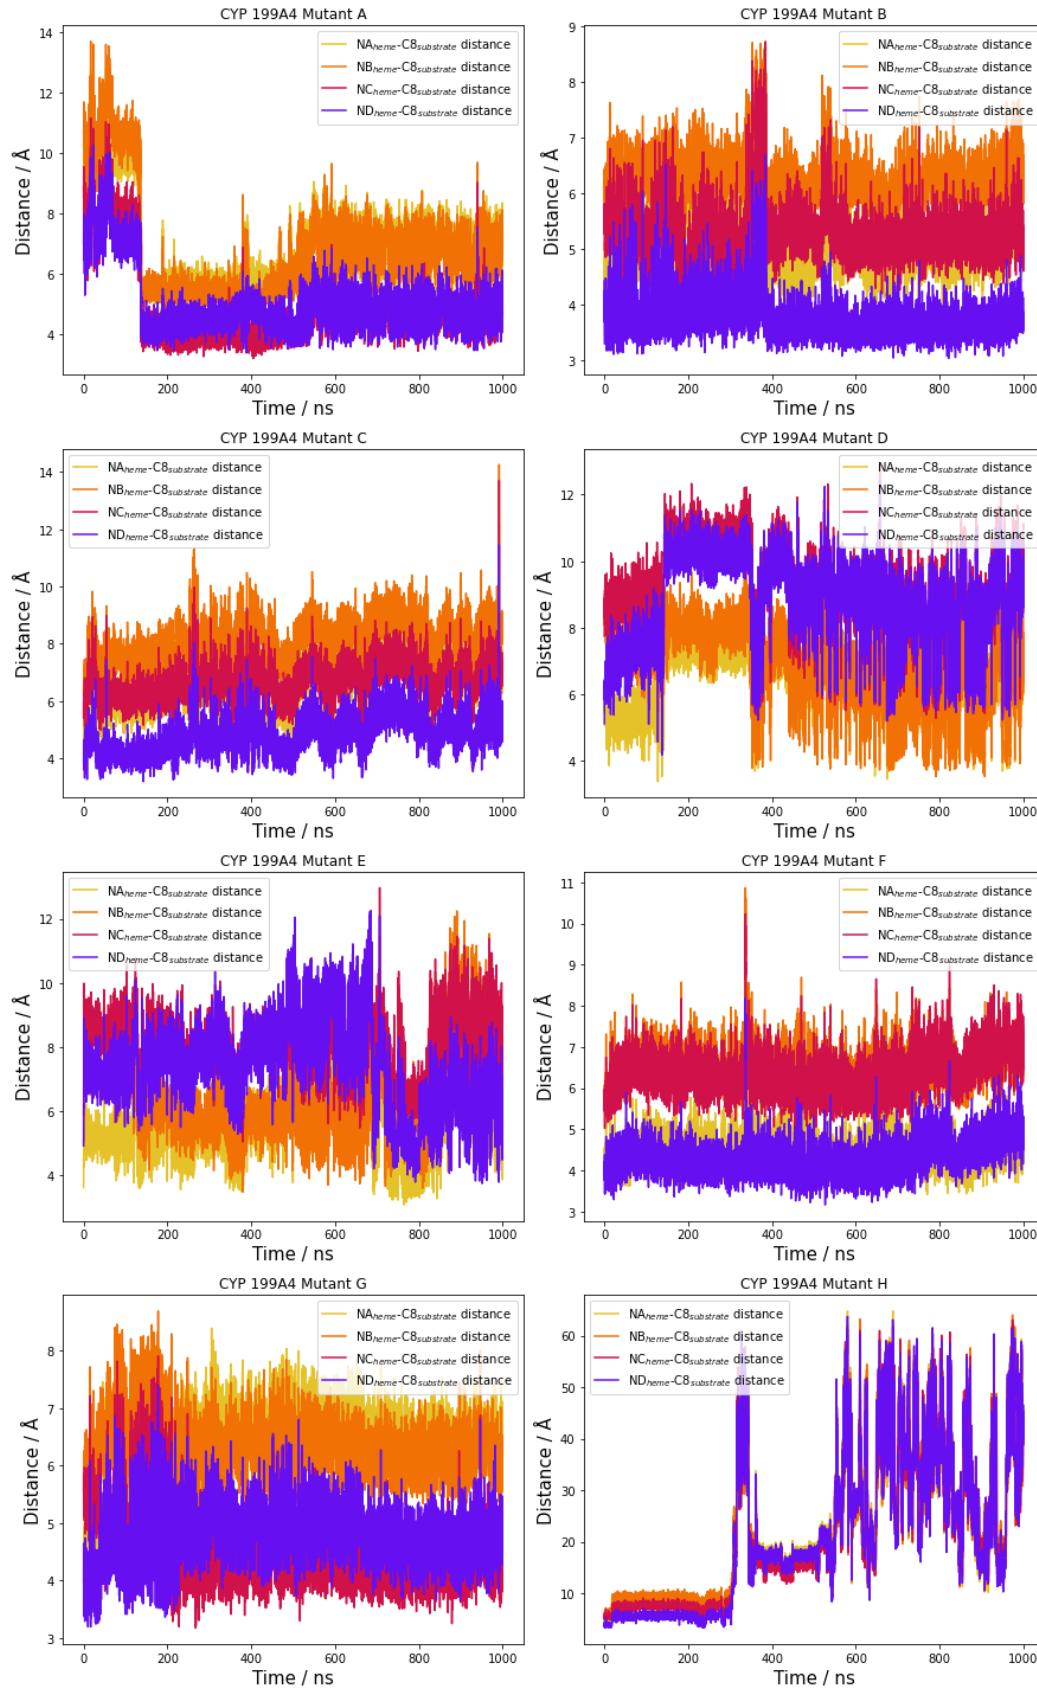

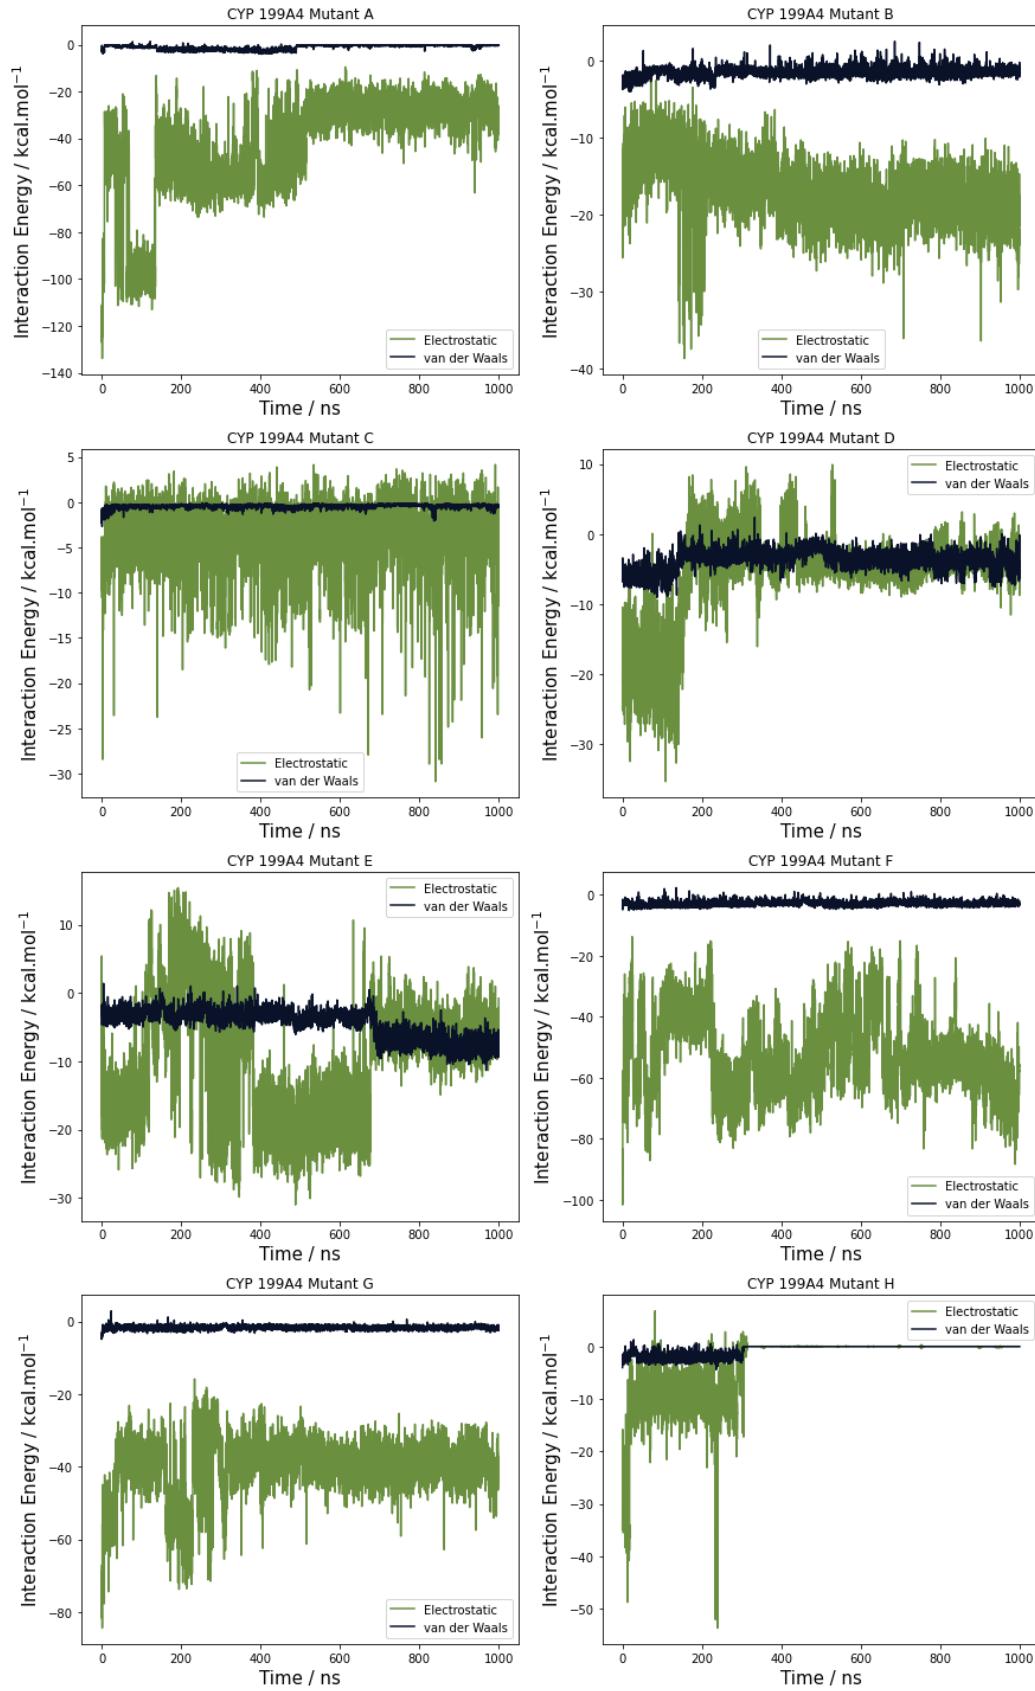

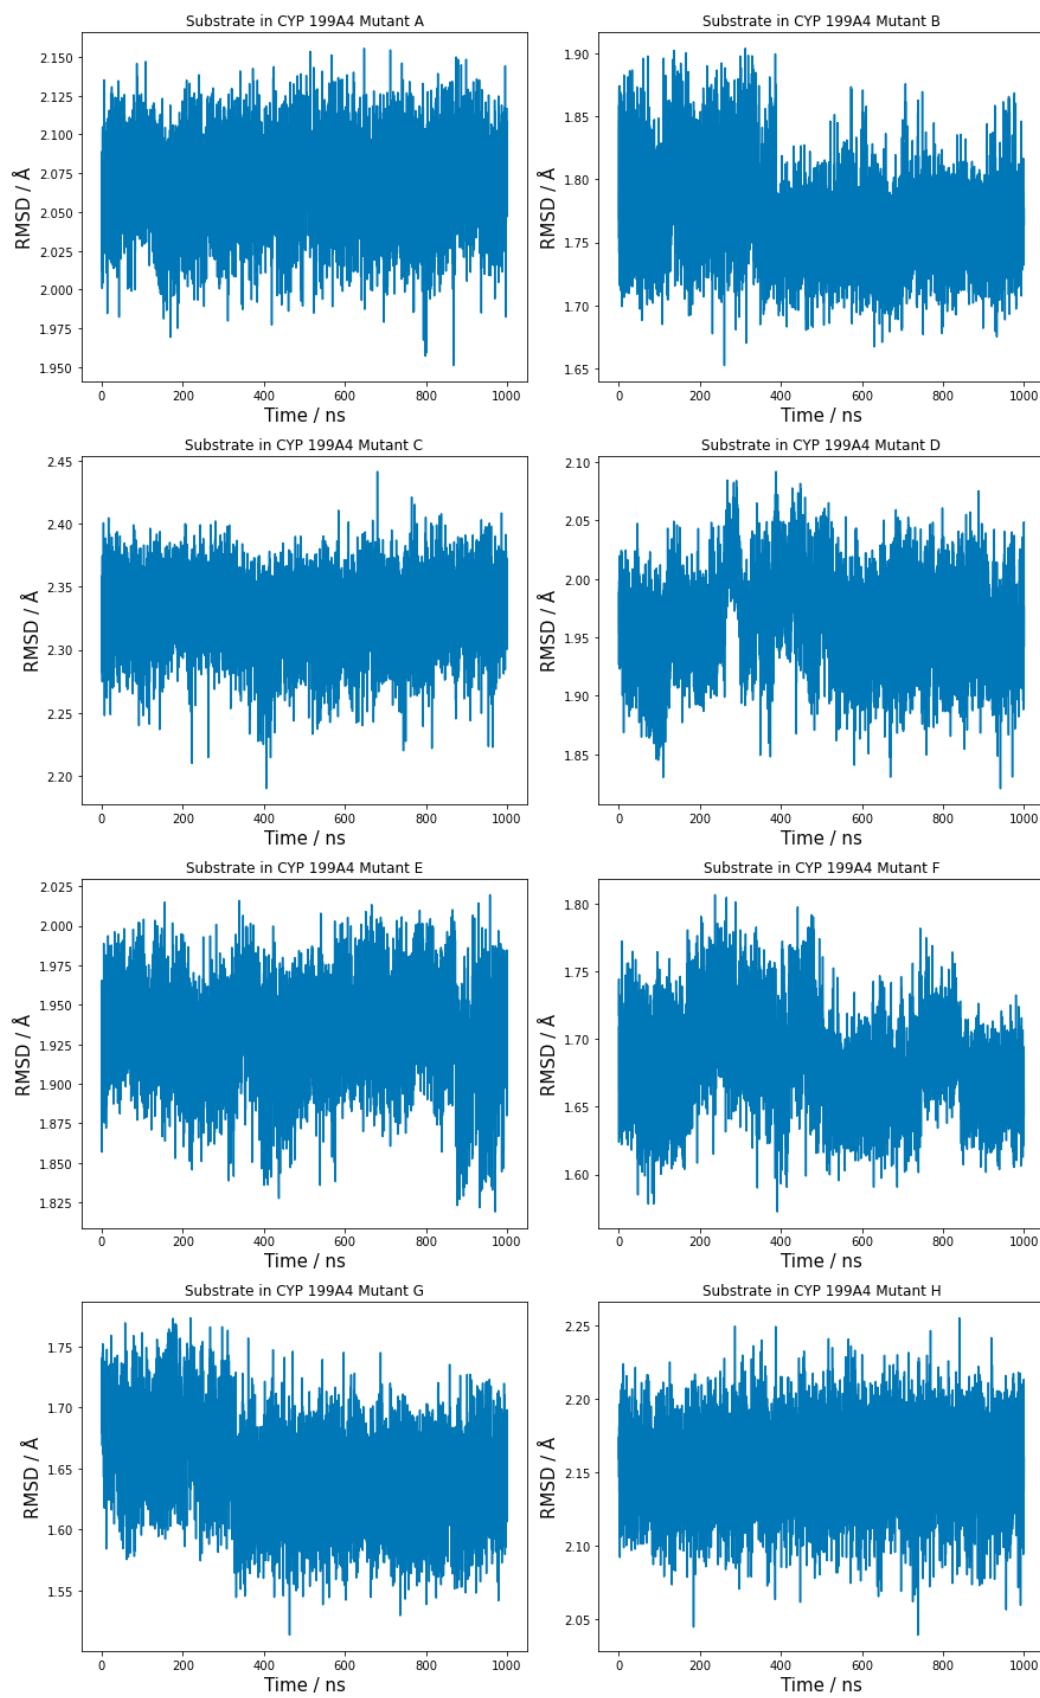

Fig. S23. Euclidean distance between  $C_{8\text{substrate}}$  and the four nitrogen atoms in the porphyrin ring of mutant CYP199A4 systems throughout 1 μs of MD production run. Top-Down and Left-Right: mutants A-H.

*Fig. S24. Interaction energies between substrate and mutant CYP199A4's active site residues throughout 1 μs of production run. Electrostatic interaction energies between substrate and active site residues (all within 8 Å from O<sub>CpdI</sub>) are in green, while van der Waals interaction energies between substrate and the three phenylalanine residues in the active site (Phe<sub>182</sub>, Phe<sub>185</sub> and Phe<sub>298</sub>) are depicted in dark blue. Top-Down and Left-right: mutants A-H.*

*Fig. S25. All-atoms RMSD of substrate (4-methoxibenzoate) in all mutant CYP199A4 systems throughout 1 μs of MD production run. Top-Down and Left-Right: mutants A-H.*

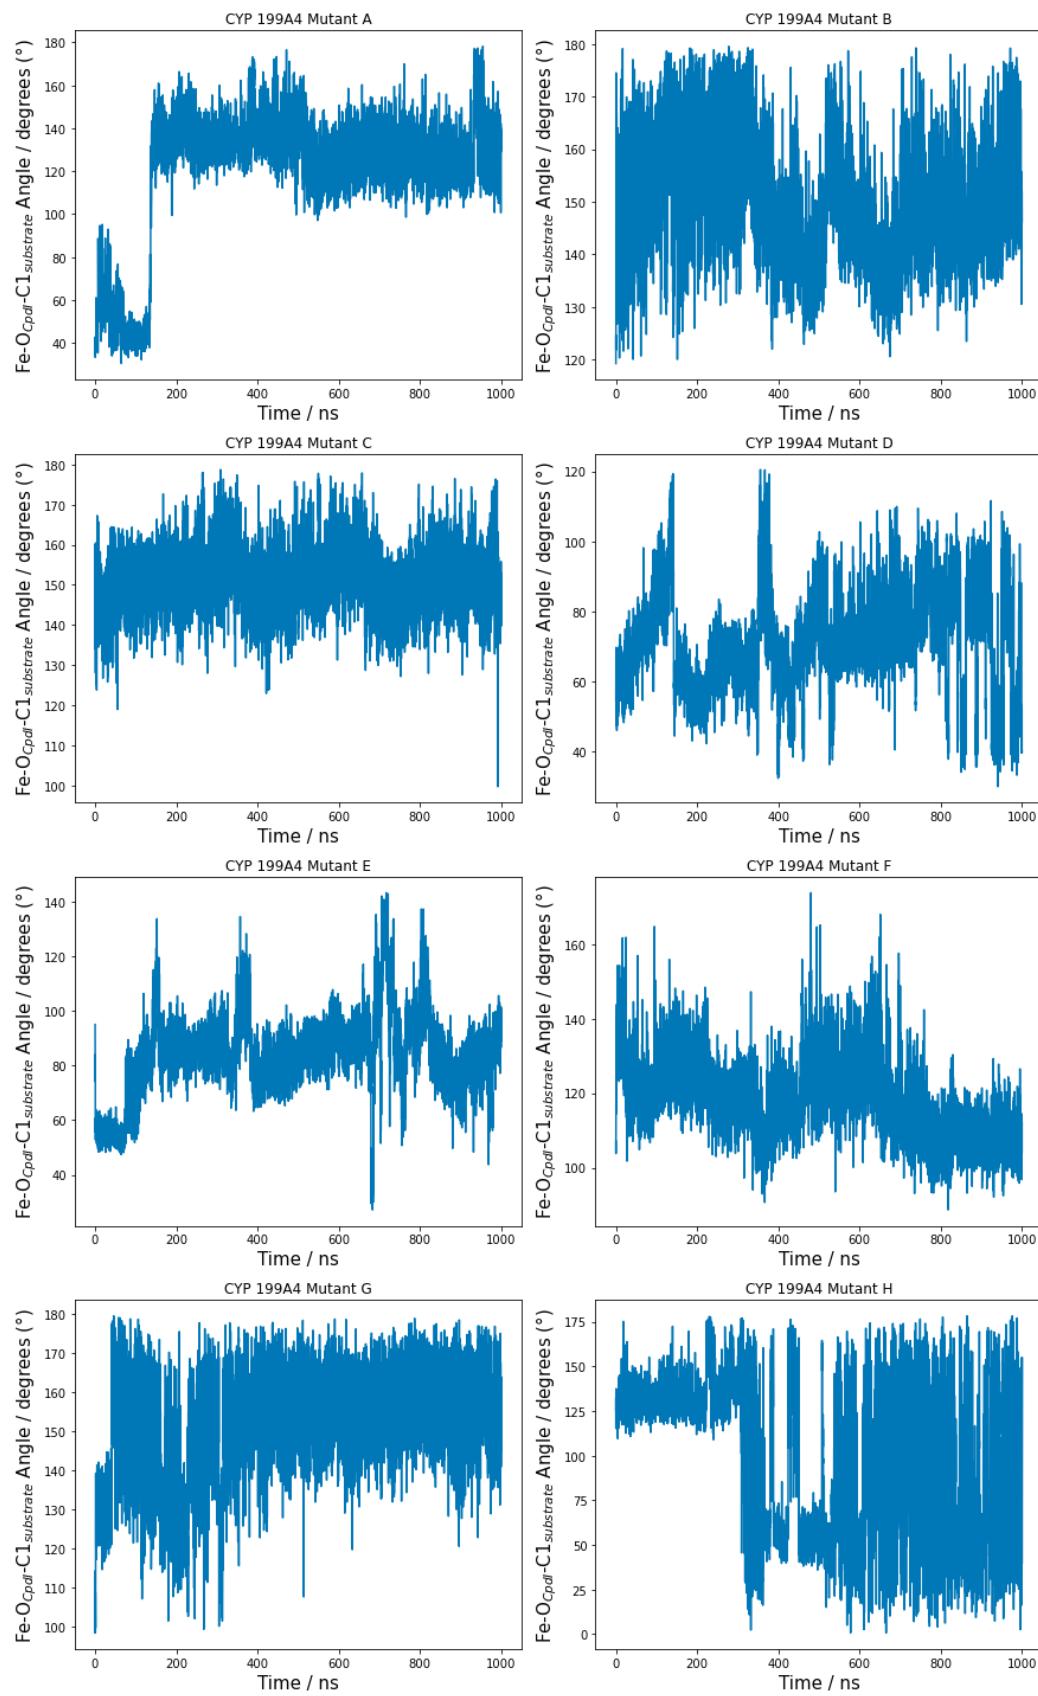

Fig. S26. Angle between Fe, O<sub>CpdI</sub> and C1<sub>substrate</sub> in the mutant CYP199A4 structures throughout 1  $\mu$ s of MD production run. Top-Down and Left-Right: mutants A-H.

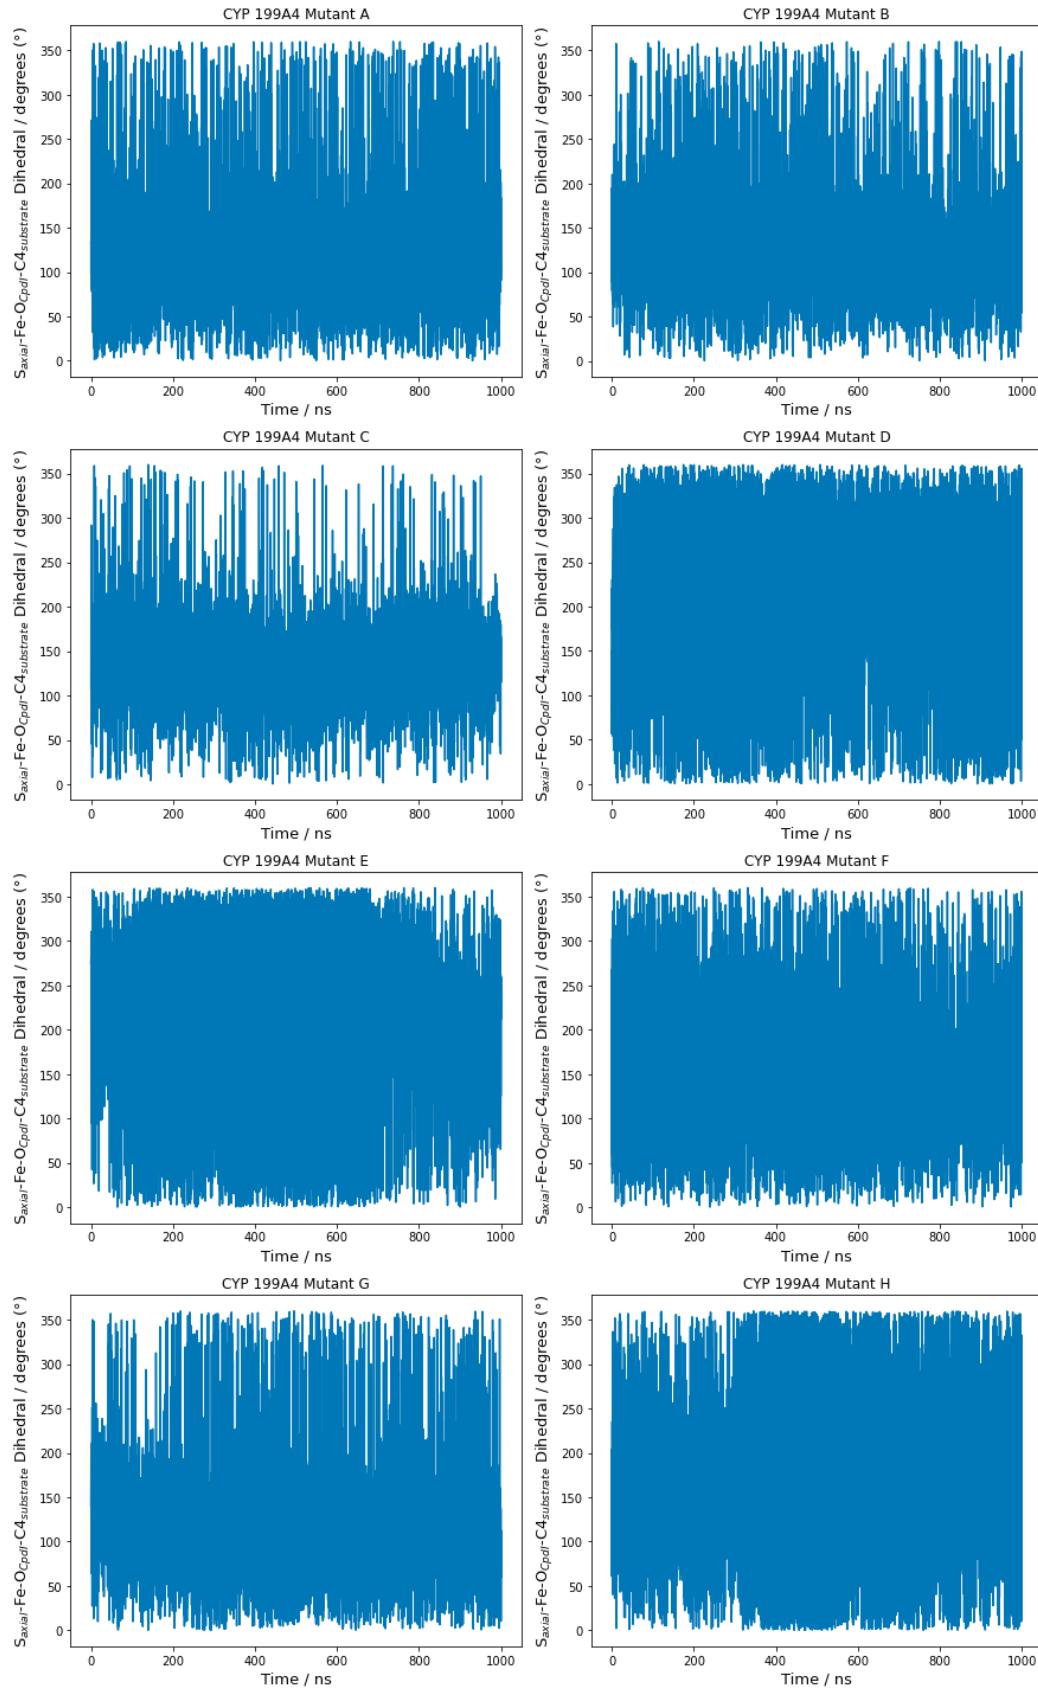

Fig. S27. Dihedral angle between  $S_{\text{axial}}$ , Fe,  $O_{\text{CpdI}}$  and  $C1_{\text{substrate}}$  in the mutant CYP199A4 structures throughout 1  $\mu$ s of MD production run. Top-Down and Left-Right: mutants A-H.

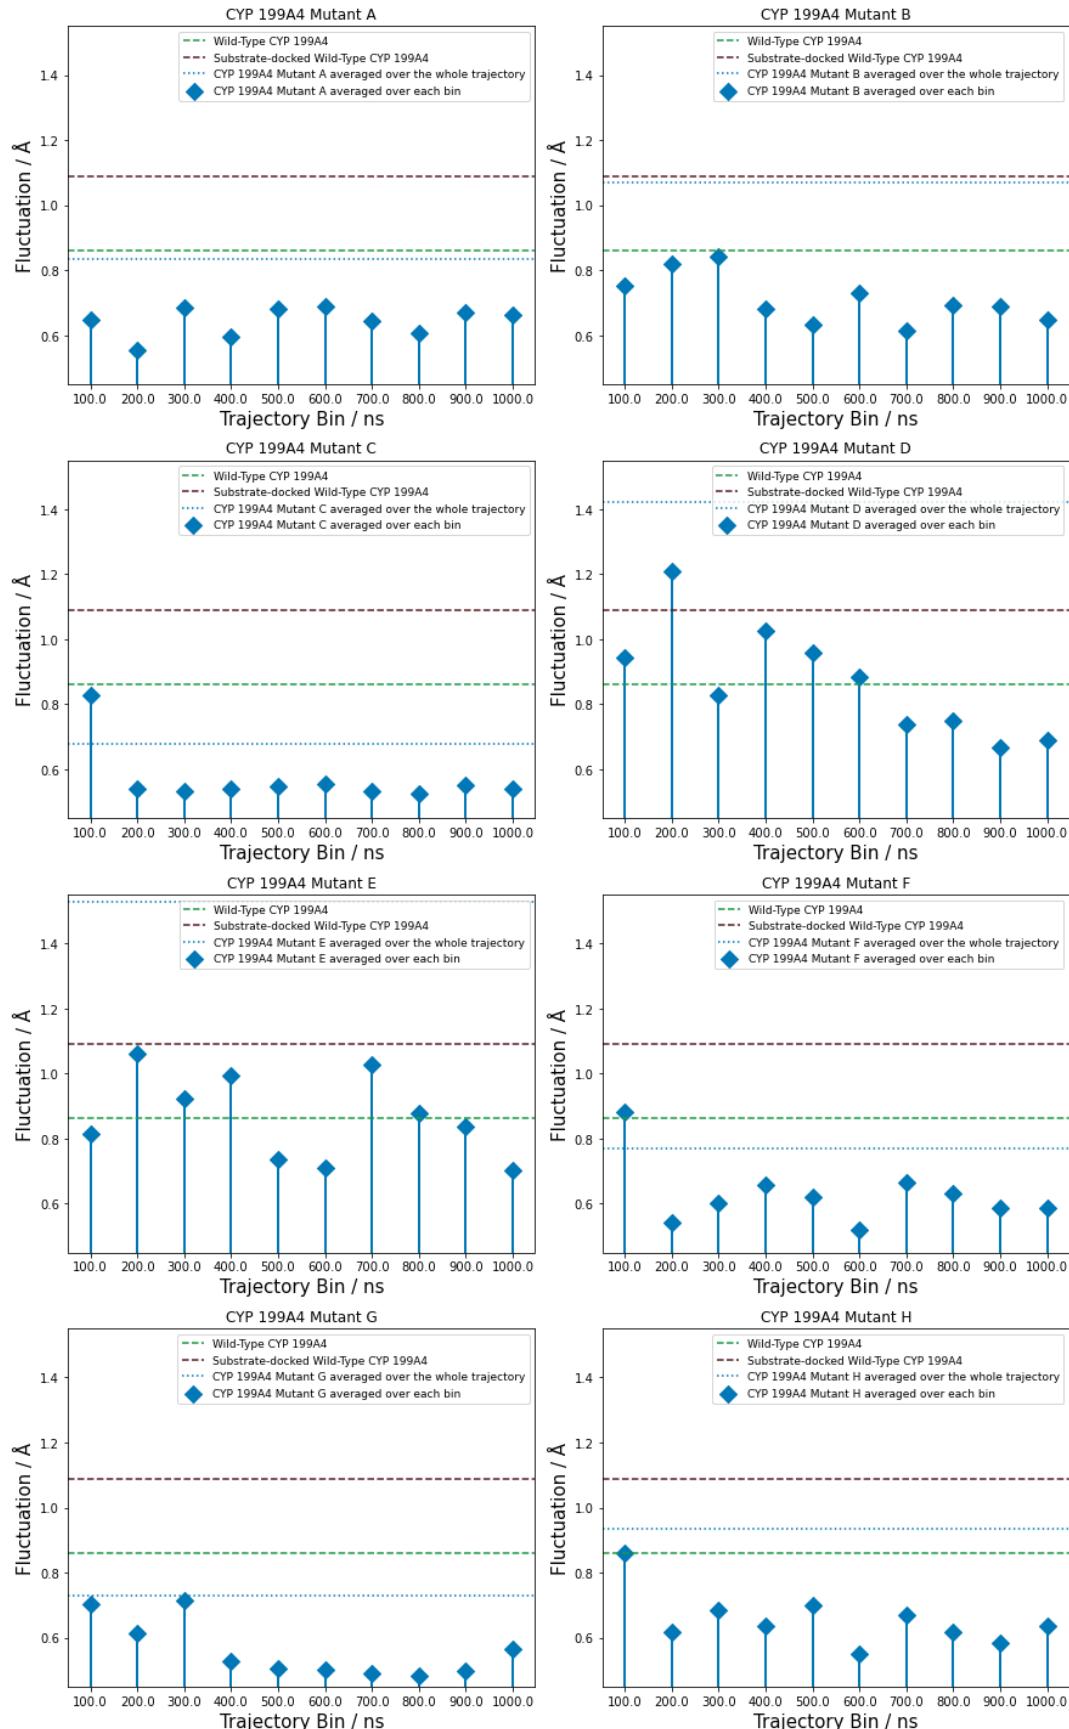

Fig. S28. RMSF of active site residues (all within 8 Å of O<sub>CpdI</sub>) from mutant CYP199A4 structures throughout 1 μs of MD production run. For comparison purposes, in each subplot there are horizontal lines that mark the RMSF of active site residues of the two wildtype CYP199A4 structures over their respective 100 ns-long MD runs Top-Down and Left-Right: mutants A-H.

## Part 2.4 Unsupervised Learning for CYP199A4 Mutant Selection

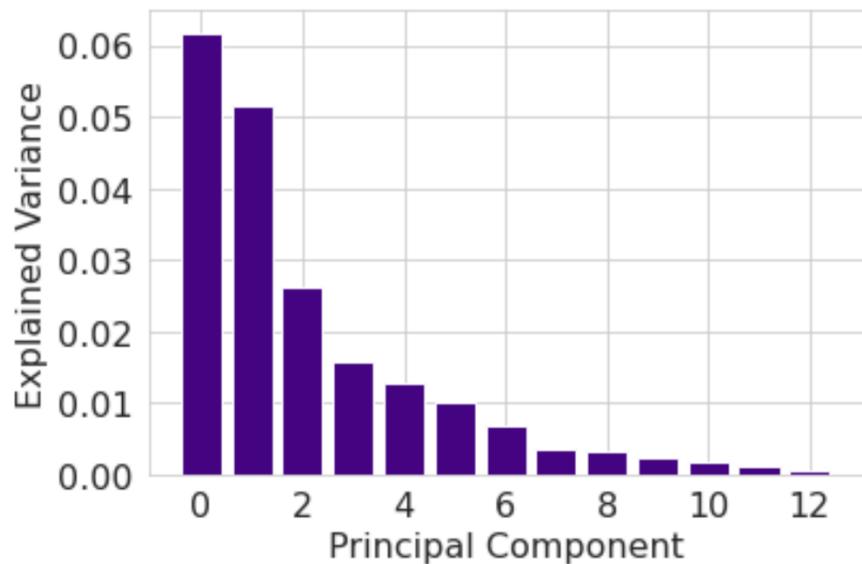

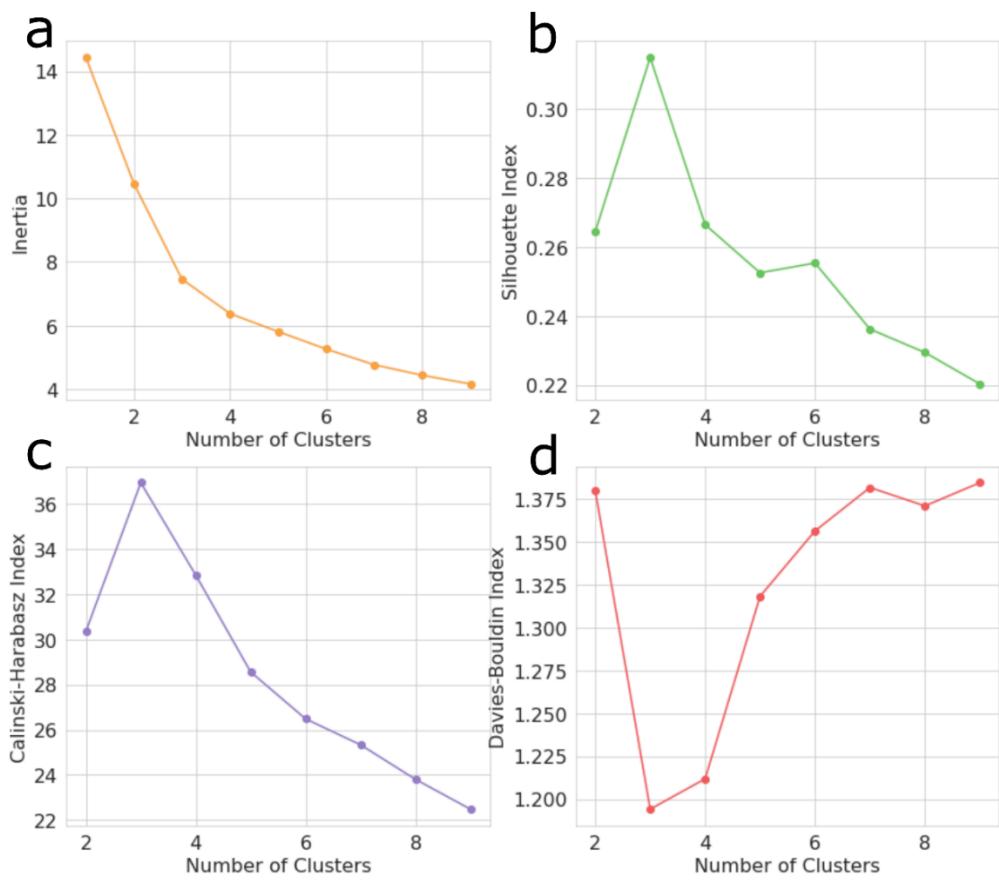

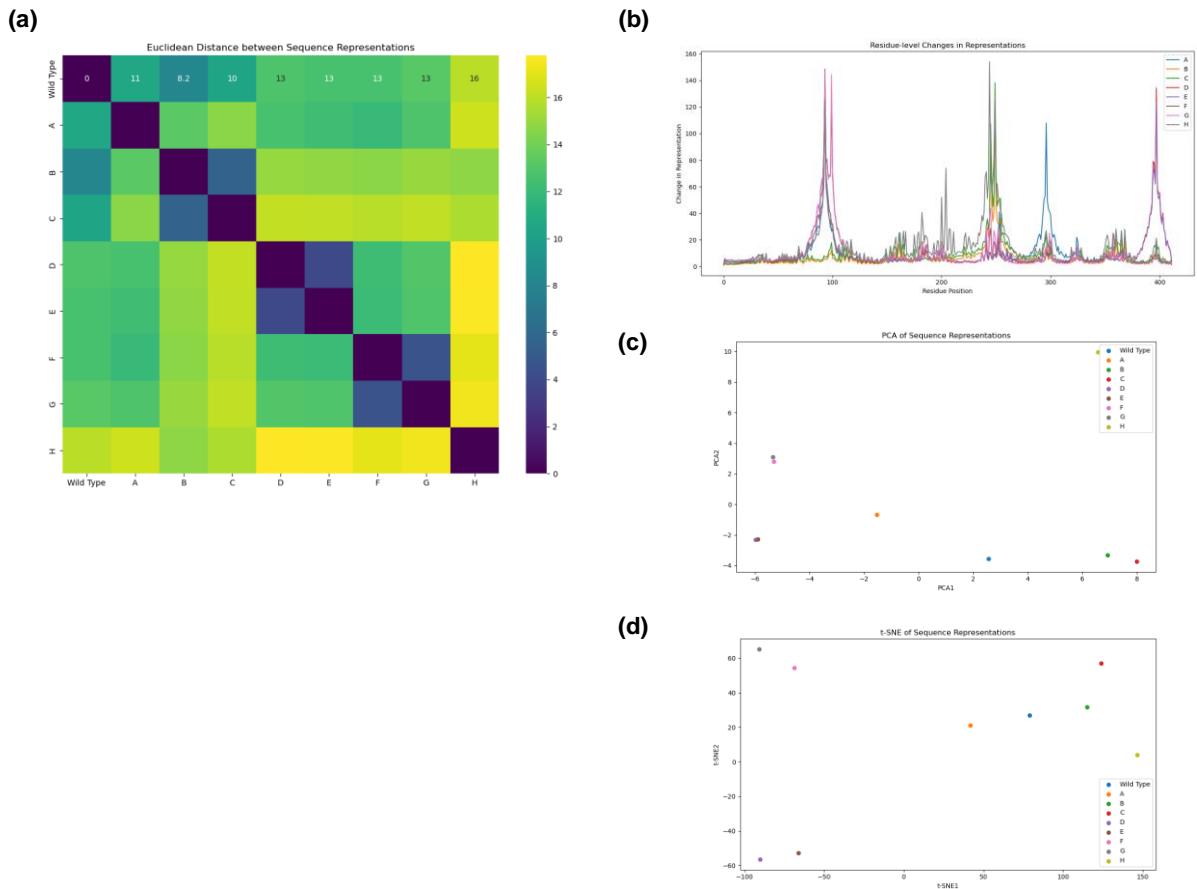

Fig. S29. Explained variance of the CYP199A4 dataset. Principal components which explained less than 0.01 of variance were discarded moving forward into the next steps. Thus, the intrinsic dimension of the dataset was determined to be 6.

*Fig. S30. Clustering metrics used to investigate the optimal grouping of datapoints from our CYP199A4, PCA-transformed, dataset: a) Inertia, or the within-cluster sum of squares, starts to moderately level off at n=3; b) Silhouette index, which indicate better clustering at higher values; c) Calinski-Harabasz index, just like the Silhouette, peaks at n=3 and represents better cluster separation at this value; d) and Davies-Bouldin index, which indicates higher quality clusters with lower values, bottoms at n=3. In conclusion, the optimal division of the data is splitting it into three distinct clusters.*

*Fig. S31. Environmental sequence modelling of WT and eight selected mutants: a) Euclidian distance plot between WT and mutant selections. This Figure shows minor structural changes upon mutation and are expected to have little impact on structure and function; b) Residue levels plot, which highlights the key residues that are affected by the mutations; c) PCA plot comparing WT and mutant structures; d) t-SNE plot comparing WT and mutant structures.*

## Part 3: QM CLUSTER CALCULATIONS

### Part 3.1 CYP255A system

#### Part 3.1.1 QM cluster energies, charges, and spin densities

**Table S2: Absolute (free) energies (in au) of UB3LYP/BS1 optimized geometries of GcoA cluster model as obtained in Gaussian-09. Also shown are the degree of spin contamination in the structures ( $S^2$  values).**

	E [BS1, au]	ZPE	G [au]	E [BS2, au]	$S^2$
