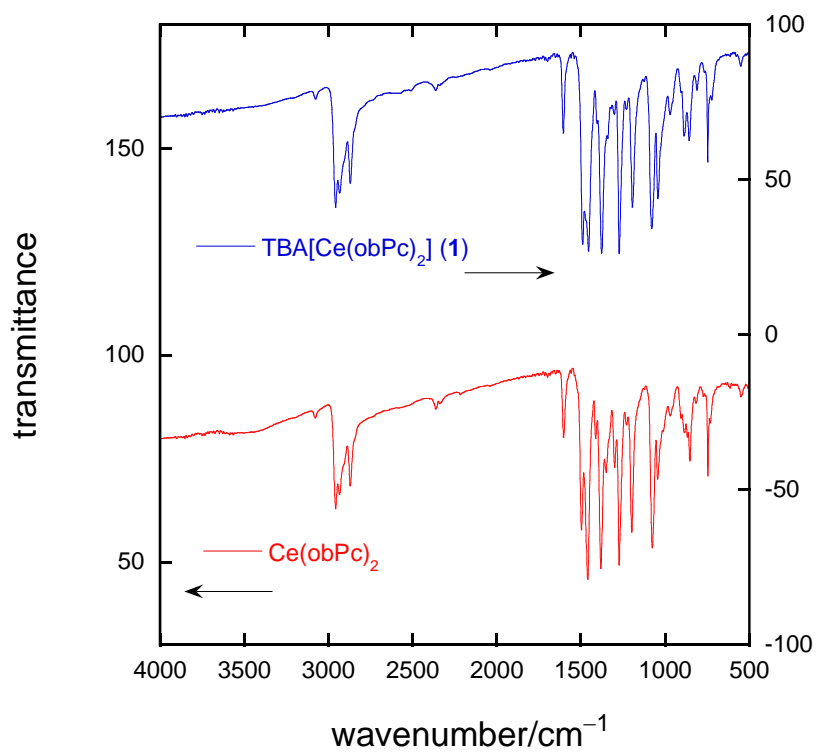

Fig. S9-3 FT-IR spectra for $\text{Ce}(\text{obPc})_2$ and $\text{TBA}[\text{Ce}(\text{obPc})_2]$ (**1**) as KBr pellets at 289 K.

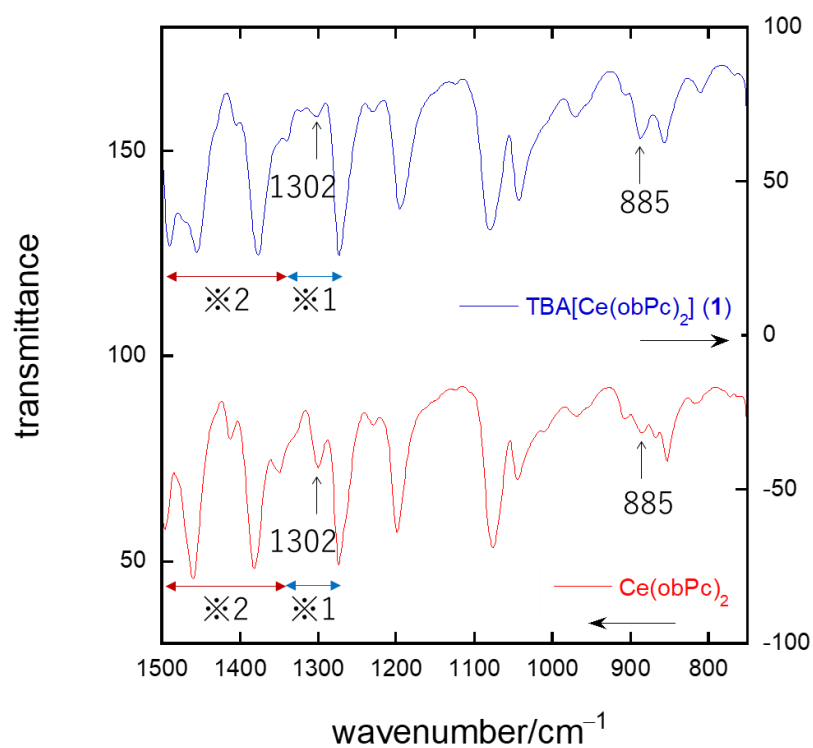

Fig. S9-4 FT-IR spectra ($750\text{--}1500\text{ cm}^{-1}$) for $\text{Ce}(\text{obPc})_2$ and $\text{TBA}[\text{Ce}(\text{obPc})_2]$ (**1**) as KBr pellets at 298 K.

※1 $1300\text{--}1350$: pyrrole stretching. ※2 $1370\text{--}1484\text{ cm}^{-1}$: isoindole stretching.⁴

Fig. S10 Schematic illustration of the intramolecular electron transfer (IET) for neutral $\text{Ce}(\text{obPc})_2$ and $\text{Ce}(\text{Pc})_2$ with the dynamic disorder (see main text).

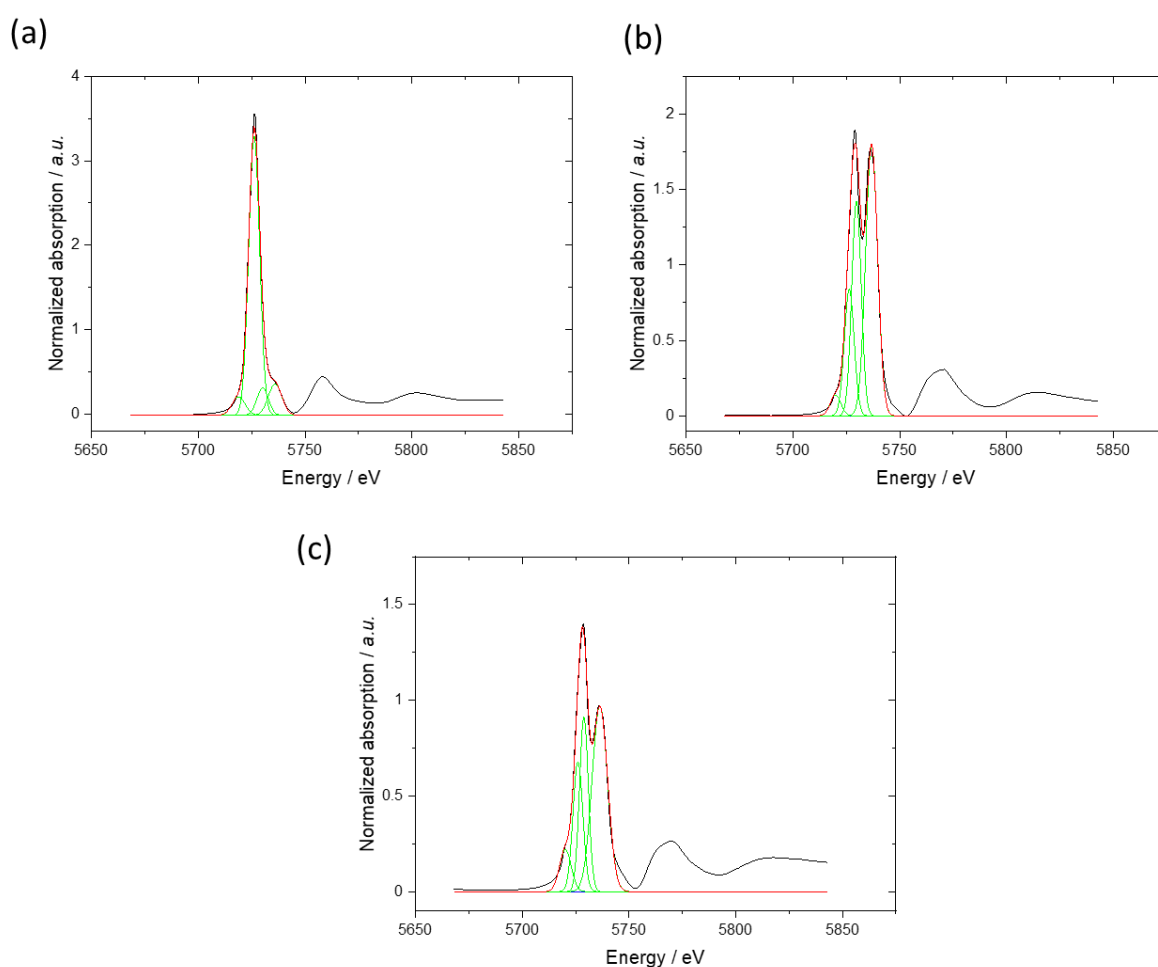

Fig. 11 Ce L_{III} -edge XANES spectra of $\text{Ce}(\text{Pc})_2$ based complexes. (a) $\text{TBA}[\text{Ce}(\text{obPc})_2]$ (**1**), (b) $\text{Ce}(\text{obPc})_2$, and (c) $\text{Ce}(\text{Pc})_2$. Deconvolution analysis was performed based on the literature.^{5,6} The solid lines show the results of estimating the components of Ce^{3+} and Ce^{4+} using a Gaussian function.

Table S4-1. Deconvolution analysis data of area ratio for the Ce(Pc)₂ based complexes in Fig. S11

Peak	Position (E/eV)	Ce(obPc) ₂	Ce(Pc) ₂	1
Pre-edge	5721	0.18	0.38	0.76
a	5726	1.0	1.0	9.6
b	5729	1.65	1.2	1.0
c	5736	2.63	2.26	1.3

Table S4-2. Deconvolution analysis data for the Ce(Pc)₂-based complexes in Fig. S11

Ce complex	method	Area ratio	Percentage(%)	Net valence of Ce ion	Method
		Ce ³⁺ :Ce ⁴⁺	Ce ³⁺ :Ce ⁴⁺		Ref.
TBA[Ce(obPc) ₂]	(A)	10.4:2.3	82:18	3.2	5
	(B)	10.6:1.3	89:11	3.1	6
Ce(obPc) ₂	(A)	1.2:4.3	22:78	3.8	5
	(B)	2.7:5.3	51:49	3.5	6
Ce(Pc) ₂	(A)	1.4:3.9	26:74	3.7	5
	(B)	2.6:4.9	53:47	3.5	6

§ Methods for estimating the valence of Ce ion vary depending on the researcher. We used two methods to estimate the Ce valence of the Ce(Pc)₂-based complexes. (A) The ratio was calculated assuming that Pre-edge and **a** are derived from Ce³⁺ (4f¹), and **b** and **c** are derived from Ce⁴⁺ (4f⁰).⁵ (B) The ratio was calculated assuming that **a** and **b** were derived from Ce³⁺ (4f¹) and **c** was derived from Ce⁴⁺ (4f⁰).⁶

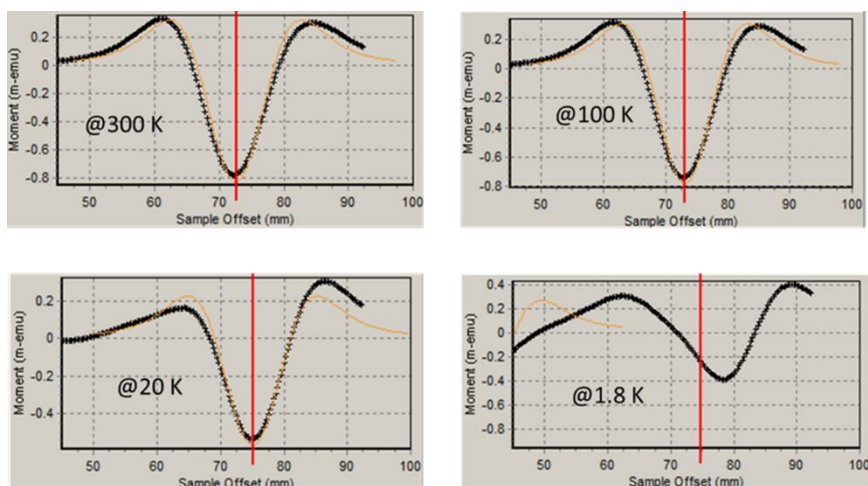

Fig. S12 In the magnetic measurements, while conducting the centering process to ascertain the precise position of the sample, response curves are procured. If the response curve manifests upward convexity, it signifies the paramagnetic nature of the sample. In contrast, the presence of downward convexity, even in strong magnetic field intensities and high temperatures nearing 2 K, denotes the diamagnetic character of the sample. Measurements of $\text{Ce}(\text{obPc})_2$ were executed at 300 K, 100 K, 20 K, and 1.8 K in a 10 kOe dc magnetic field. In $\text{Ce}(\text{obPc})_2$, diamagnetic response curves were generated across all temperature regimes. Samples that were prepared using a Ce^{3+} precursor showed no traces of Ce^{3+} in the sample (see Experimental section in main text).

Fig. S13 M - H curve for powder samples of $\text{Ce}(\text{Pc})_2$. It exhibits paramagnetic properties at 2 K. On the other hand, it exhibited diamagnetic properties above 10 K. Samples that were prepared using a Ce^{4+} precursor showed traces of Ce^{3+} in the sample (see Experimental section in main text). Thus, both $\text{Ce}(\text{obPc})_2$ and $\text{Ce}(\text{Pc})_2$ are in a $\text{Ce}^{4+}/\text{Ce}^{3+}$ mixed valence state, with the paramagnetic signature observed for $\text{Ce}(\text{Pc})_2$ indicative of a higher ratio of Ce^{3+} in comparison to $\text{Ce}(\text{obPc})_2$ (Table S4).

Fig. S14 Reduced magnetization (M versus HT^{-1}) for powder samples of **2**.

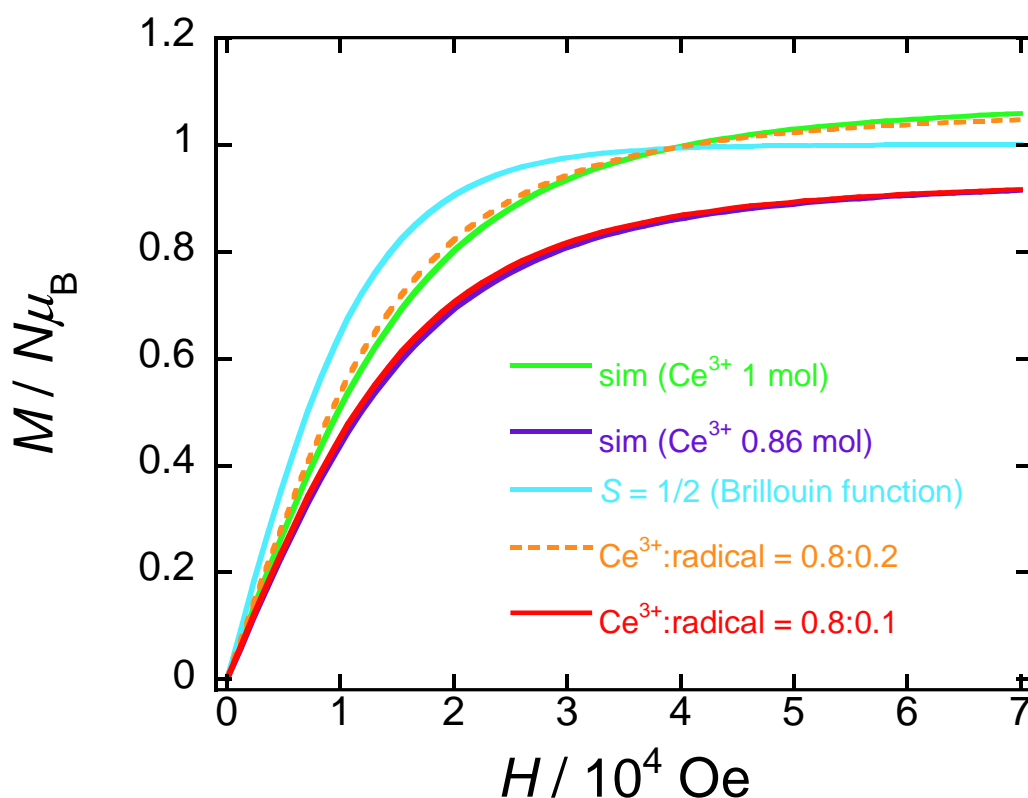

Fig. S15 As a supplement to Fig. 5, simulation results of the M - H curve are presented. The simulation curve indicates that the yellow-green line represents 1 mol of Ce^{3+} using LFPs. The cyan line represents a radicals delocalized on Pc ligands using Brillouin function with $S = 1/2$ (1 mol). The purple line, using LFPs with 0.86 mol of Ce^{3+} , reproduced the experimental data (see Fig. 5). This is effective when assuming $\text{Ce}^{3+}:\text{Ce}^{4+} = 0.8:0.2$ based on XANES spectrum analysis (Table S4-2) and attributing magnetic properties to the Ce^{3+} component.

On the other hand, the orange dashed line represents the result of simulation at $[\text{Ce}^{3+}(\text{obPc})^{2-}(\text{obPc})^{2-}]^- : [\text{Ce}^{4+}(\text{obPc})^{2-}(\text{obPc})^{3-}]^- = \text{Ce}^{3+}:\text{radical} = 0.8:0.2$ based on XANES spectrum analysis, which fails to reproduce the experimental data (see Fig. 5). The experimental values can be nearly reproduced by the red line ($\text{Ce}^{3+}:\text{radical} = 0.8:0.1$). These simulations simply add together Ce^{3+} and radical components. Considering the XANES spectrum of the neutral species (Table S4-2) and the results of M - H (Fig. S13), the magnetisation value of the radicals in the $[\text{Ce}^{4+}(\text{obPc})^{2-}(\text{obPc})^{3-}]^-$ unit resulting from intramolecular electron transfer (IET) are lower than the ratio obtained from XANES spectrum.

(b) ν dependences of the (top) in-phase (χ_M') and (bottom) out-of-phase (χ_M'') ac magnetic susceptibilities of **1** in an H_{dc} of 250 Oe. The solid lines are guides only.

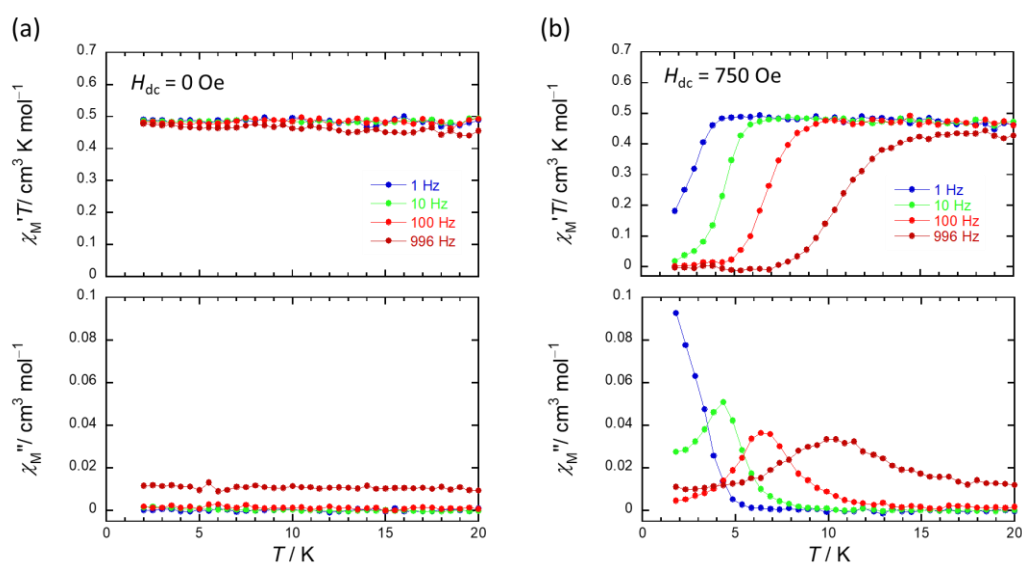

Fig. S16-2 (a) Frequency (ν) dependences of the (top) in-phase (χ_M') and (bottom) out-of-phase (χ_M'') ac magnetic susceptibilities of **2** in an H_{dc} of zero Oe. (b) ν dependences of the (top) in-phase (χ_M') and (bottom) out-of-phase (χ_M'') ac magnetic susceptibilities of **2** in an H_{dc} of 750 Oe. The solid lines are guides only.

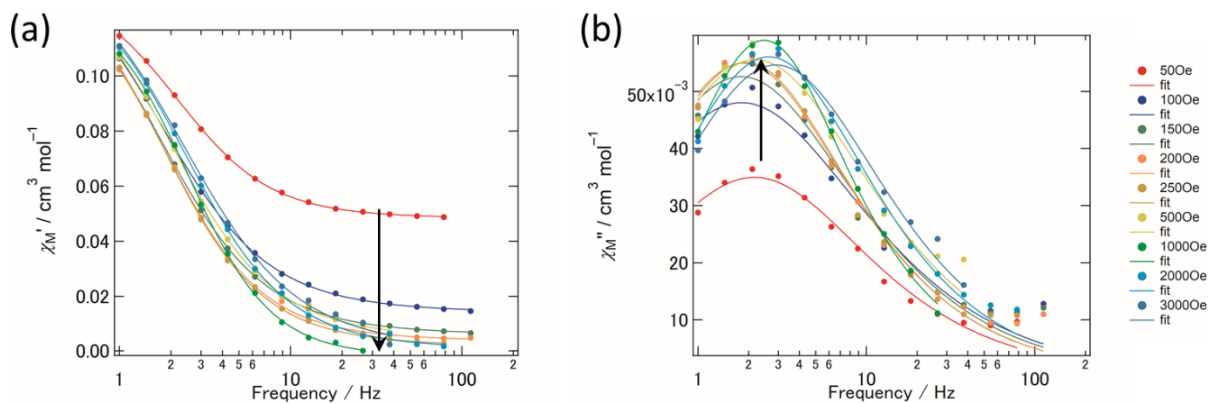

Fig. S17 Frequency (ν) dependences of the (a) in-phase (χ_M') and (b) out-of-phase (χ_M'') ac magnetic susceptibilities of **1** at 4 K in several dc magnetic fields. The solid lines were fitted by using eqns. S1–S3.

Fig. S18 Frequency (ν) dependences of the (a) in-phase (χ_M') and (b) out-of-phase (χ_M'') ac magnetic susceptibilities of **2** at 4 K in several dc magnetic fields. The solid lines were fitted by using eqns. S1–S3.

Generalized Debye model (eqns. S1–S3)⁷

The real (χ_M') and imaginary parts (χ_M'') of the ac magnetic susceptibilities are determined by using eqns. S2 and S3, respectively.

$$\chi_{total}(\omega) = \chi_S + \frac{\chi_T - \chi_S}{1 + (i\omega\tau)^{1-\alpha}} \quad (\text{eqn. S1})$$

$$\chi'(\omega) = \chi_S + (\chi_T - \chi_S) \frac{1 + (\omega\tau)^{1-\alpha} \sin(\pi\alpha/2)}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2-2\alpha}} \quad (\text{eqn. S2})$$

$$\chi''(\omega) = (\chi_T - \chi_S) \frac{(\omega\tau)^{1-\alpha} \cos(\pi\alpha/2)}{1 + 2(\omega\tau)^{1-\alpha} \sin(\pi\alpha/2) + (\omega\tau)^{2-2\alpha}} \quad (\text{eqn. S3})$$

Fig. S19 H_{dc} dependence (zero–4000 Oe) of τ for **1** and **2** at 4 K.

Table S7. Optimised parameters of **2** in Fig. 6a

complex	a ₁	a ₂	b	c
2	55.187	0.0010259	4.523e-14	24.99

§ Optimized parameters for **1** are not listed because there is no data up to high magnetic fields and large error bars.

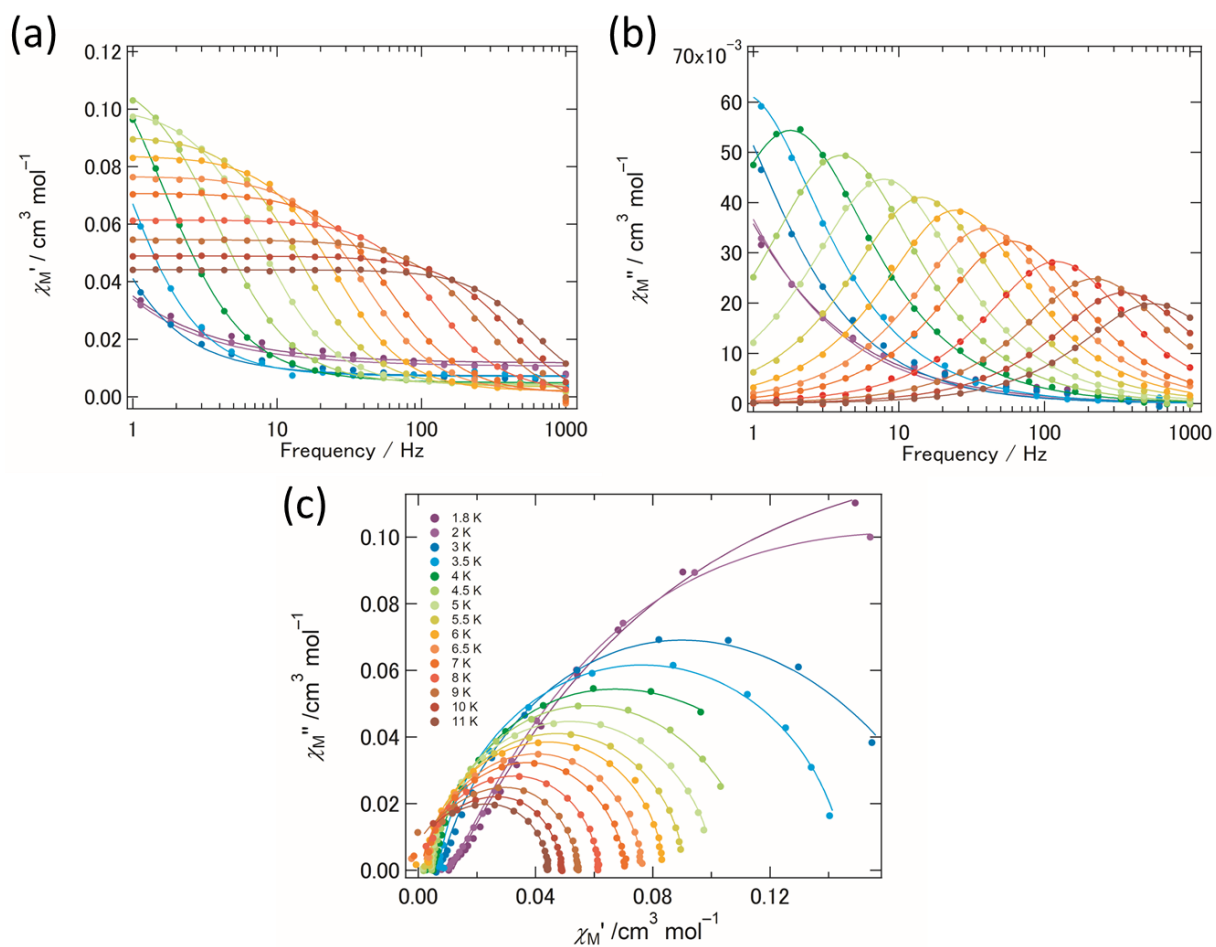

Fig. S20 Frequency (ν) and temperature (T) dependences of the (a) in-phase (χ_M') and (b) out-of-phase (χ_M'') ac magnetic susceptibilities of **1** in an H_{dc} of 250 Oe. The solid lines were fitted by using eqns. S1–S3. The semicircular Argand plots with the small α parameters (0.02–0.28) confirm that slow magnetic relaxation occurs via a single process.

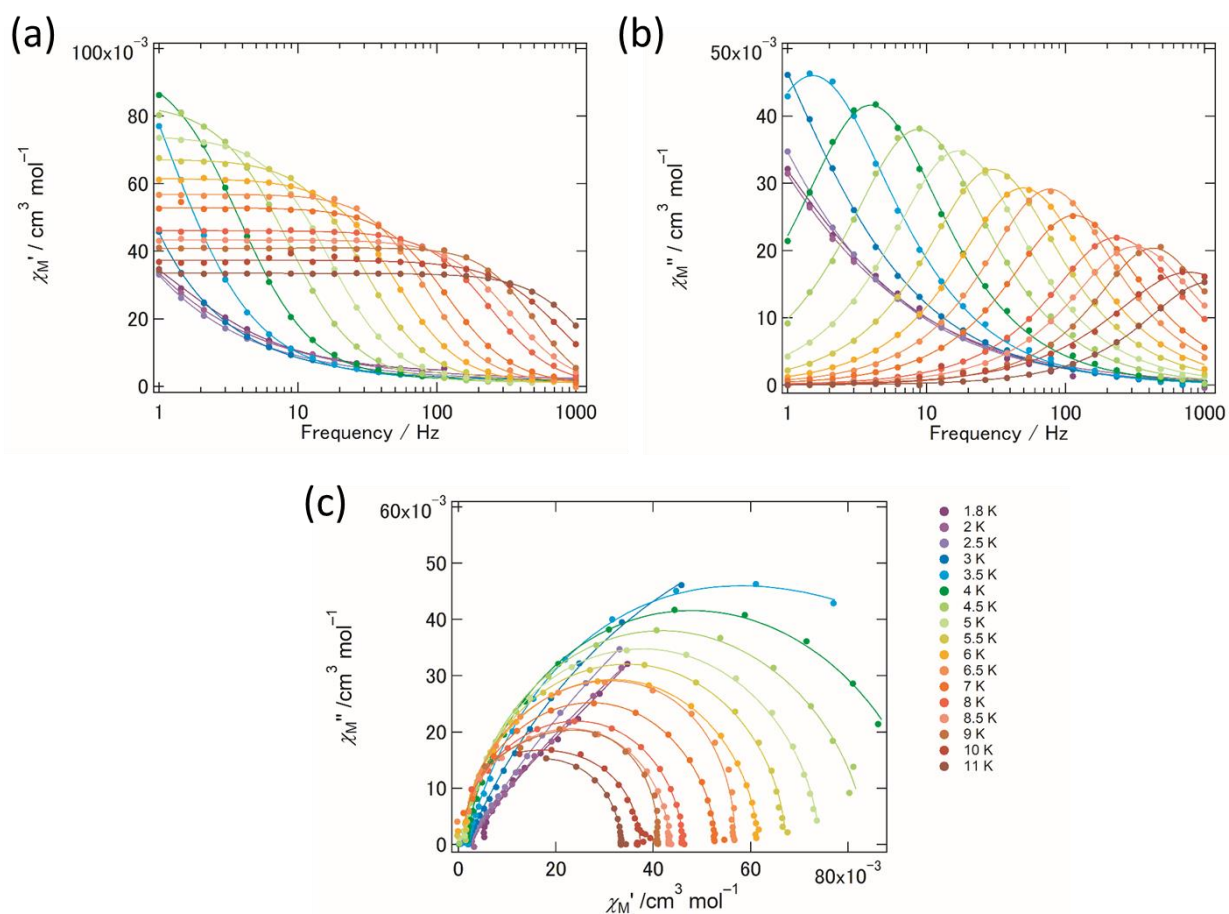

Fig. S21 Frequency (ν) and temperature (T) dependences of the (a) in-phase (χ_M') and (b) out-of-phase (χ_M'') ac magnetic susceptibilities of **2** in an H_{dc} of 750 Oe. The solid lines were fitted by using eqns. S1–S3. The semicircular Argand plots with the small α parameters (0.002–0.28) confirm that slow magnetic relaxation occurs via a single process (> 3 K).

Fig. S22 Frequency (ν) and temperature ($T = 11\text{--}20$ K) dependences of the (a) in-phase (χ_M') and (b) out-of-phase (χ_M'') ac magnetic susceptibilities of **2** in an H_{dc} of 750 Oe. The solid lines were fitted by using eqns. S1–S3.

Fig. S23 An Arrhenius plot of **1** (open square) and **2** (open circles), for which the τ values were obtained from χ_M'' versus ν plots. The solid lines were fitted by using $\tau^{-1} = CT^m$, respectively. See main text.

Fig. S24 Magnetic axis of the ground doublet of $[\text{Ce}(\text{Pc})_2]^-$ (left) and $[\text{Ce}(\text{obPc})_2]^-$ (right).

Fig. S25-1 Ligand field splitting of $[\text{Ce}(\text{Pc})_2]^-$. The arrows indicate the relaxation pathway with the transition magnetic moment in units of μ_B .

Fig. S25-2 Ligand field splitting of $[\text{Ce}(\text{obPc})_2]^-$. The arrows indicate the relaxation pathway with the transition magnetic moment in units of μ_B .

Table S7. Energy levels of ${}^2F_{5/2}$ states

	Energy / cm ⁻¹	Energy / cm ⁻¹
	$[\text{Ce}(\text{Pc})_2]^-$	$[\text{Ce}(\text{obPc})_2]^-$
w.f. 1	0	0
w.f. 2	0	0
w.f. 3	921	955
w.f. 4	921	955
w.f. 5	958	1047
w.f. 6	958	1047
