HSA binding studies

Fluorescence quenching is described by the Stern–Volmer equation [1]:

$$F_0/F = 1 + k_q \tau_0 [Q] = 1 + K_{sv}[Q] \quad (\text{S1})$$

where F_0 is the emission intensity in the absence of the compound, F is the emission intensity in the presence of the compound, K_{sv} is the Stern–Volmer quenching constant, k_q is the bimolecular quenching constant, τ_0 (10^{-8} s) [2] is the lifetime of the fluorophore in the absence of the quencher, and $[Q]$ is the concentration of the quencher (complex). The K_{sv} value is determined as the slope from the plot of F_0/F versus $[Q]$ (**Figs. S7-S9**).

The binding constant (K) and binding stoichiometry (n) of the HSA-complex system can be estimated from the Scatchard equation [1] using the fluorescence intensity data:

$$\log (F_0 - F)/F = \log K_b + n \log [Q] \quad (\text{S2})$$

The values of K_b and n were determined from the intercept and slope of the plots of $\log (F_0 - F)/F$ vs. $\log [Q]$.

DNA-binding studies

Fluorescence spectroscopy

The relative binding of the complexes to the CT DNA is described by the Stern-Volmer equation [1], in the same way as described for the HSA binding studies:

$$F_0/F = 1 + K_{sv}[Q] \quad (\text{S1})$$

where F_0 and F are the emission intensities in the absence and in presence of the quencher (complexes **Rh1-Rh4**), respectively, $[Q]$ is the total concentration of the quencher and K_{sv} is the Stern-Volmer quenching constant, which can be determined from the slope of the plot of F_0/F vs. $[Q]$ (**Figs. S10-S12**).

Absorption spectroscopy

In order to quantitatively compare the binding strength of the complexes, the intrinsic binding constants K_b were determined by observing the changes in absorbance at the MLCT band with increasing concentration of CT DNA using the Wolfe–Shimmer equation [3]:

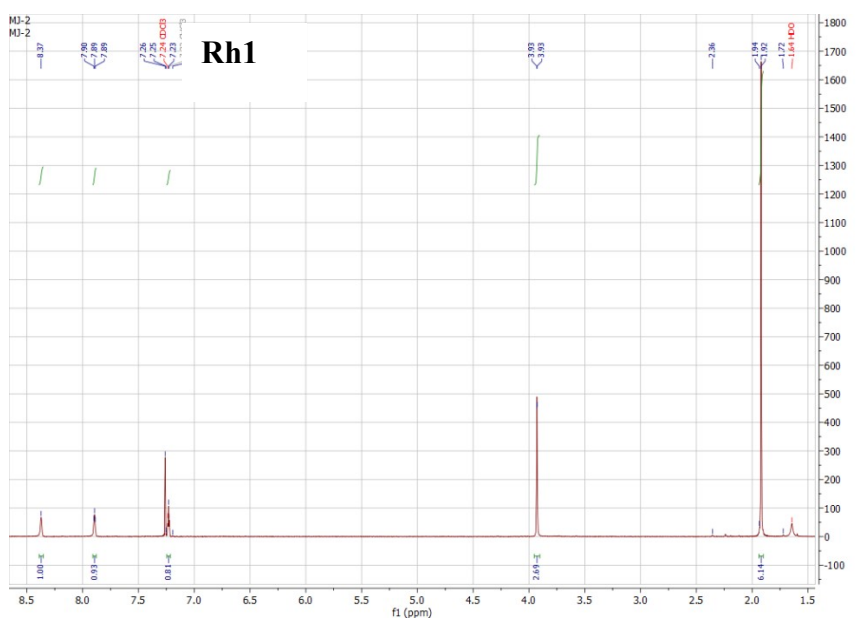

$$[\text{DNA}]/(\varepsilon_A - \varepsilon_f) = [\text{DNA}]/(\varepsilon_b - \varepsilon_f) + 1/[K_b(\varepsilon_b - \varepsilon_f)] \quad (\text{S3})$$

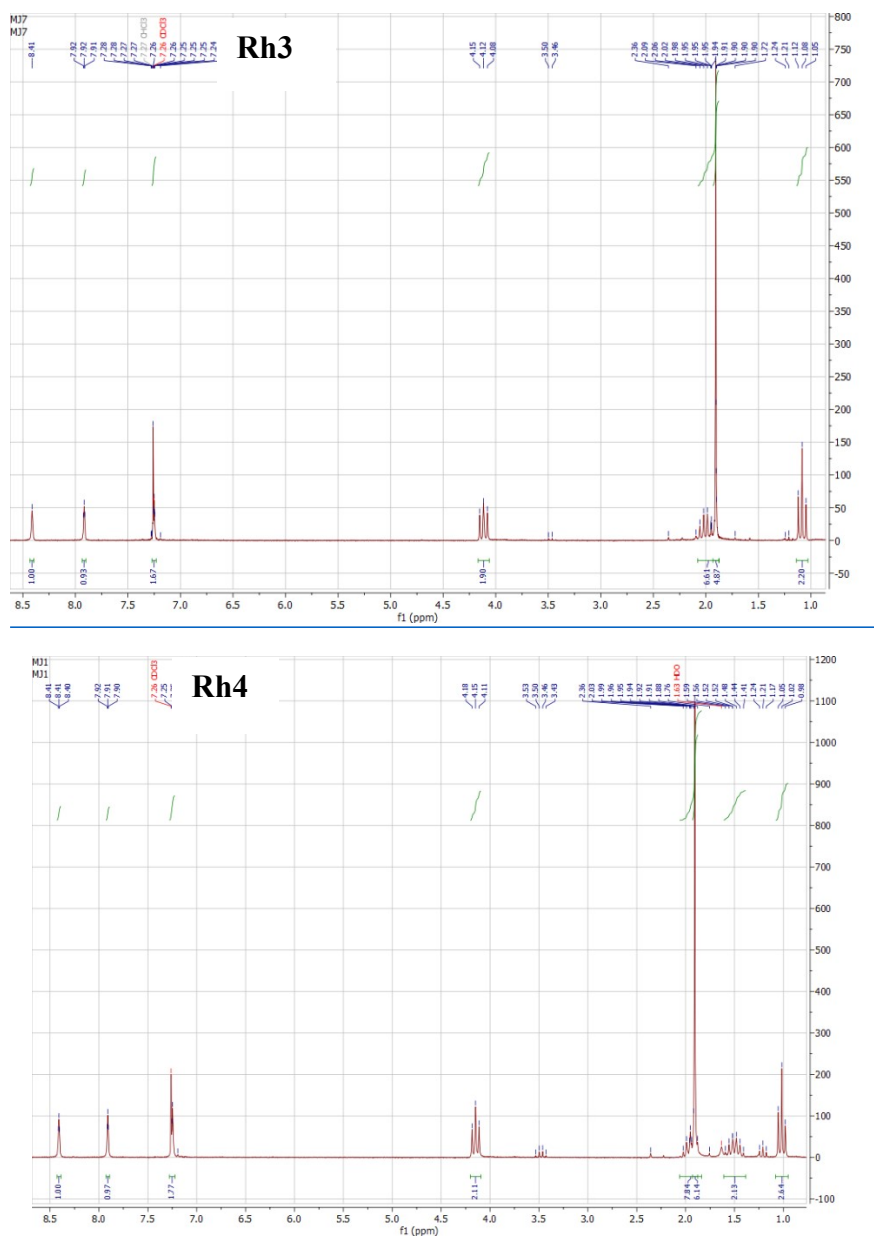

K_b is given by the ratio of the slope to the y -intercept in the plots $[\text{DNA}]/(\varepsilon_A - \varepsilon_f)$ vs. $[\text{DNA}]$ (**Fig. S13**), where $[\text{DNA}]$ is the DNA concentration in base pairs and ε_A , ε_f and ε_b are the apparent, free and fully bound complex absorption coefficients, respectively. The apparent extinction coefficient, ε_A , is determined by calculating $A_{\text{obsd}}/[\text{complex}]$. ε_f and ε_b correspond to

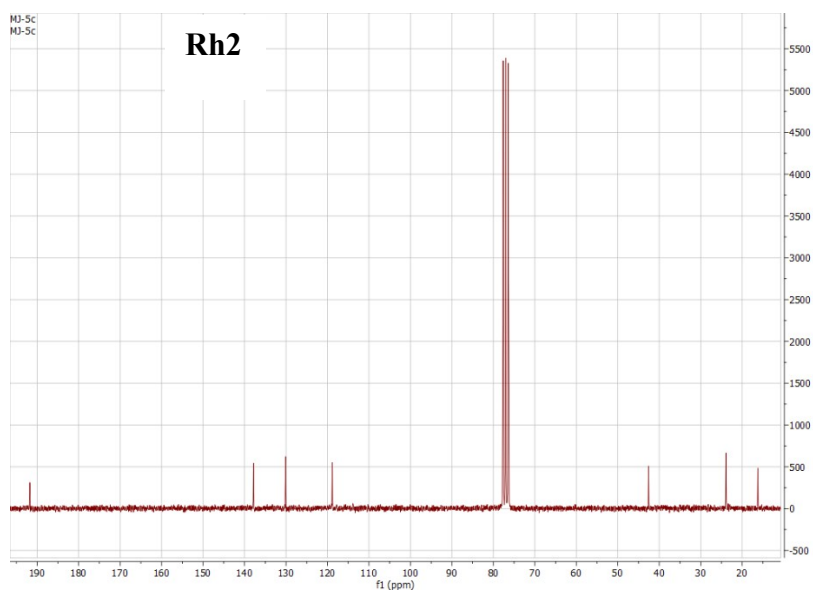

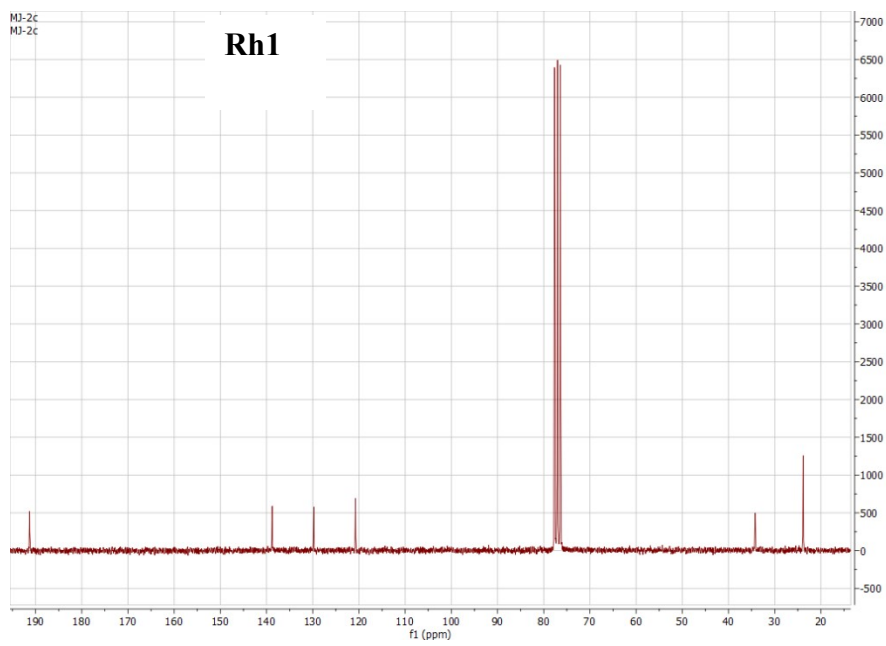

the extinction coefficient of the bound form of the complex and the extinction coefficient of the free complex.
