The effect of the wettability on protein adhesion

Supplementary Figure 1 illustrates the contact angles observed on all the different surfaces used. Bare PDMS exhibited the highest contact angle of 88.7°, indicative of its hydrophobic nature. However, upon plasma activation, the contact angle of PDMS decreased significantly to 57.2°. Further functionalization of the plasma activated PDMS with APTMS resulted in a slight decrease in the contact angle to 74.2°, while PEIGA functionalization led to a more substantial reduction, bringing the contact angle down to 46.7°. The plastic substrate displayed a contact angle of 55.9°, indicative of mild hydrophobicity, and comparable to the contact angle of plasma activated PDMS.

Next, we examined the effects of different adhesion proteins on surface wettability. Regardless of the specific adhesion protein or mixture used, the contact angles consistently decreased to a range between 35° and 9°, rendering all surfaces hydrophilic and suitable for cellular adhesion. Although no significant differences were detected between the different coatings, the overall trend clearly demonstrated the impact of activation, functionalization, and coating on the wettability of PDMS and plastic surfaces. This was highlighted by the notable decrease in contact angles, affirming the importance of these treatments in enhancing the surfaces for cellular applications.

Supplementary Figure 1. Contact angle in different surfaces. The bars on the left show the contact angle on different polymers without any adhesion proteins. The bars on the right display the contact angle on functionalized and unfunctionalized substrates with adhesion proteins. Unfunctionalized PDMS with coating is shown in bars without patterns. PEIGA-functionalized PDMS is shown in bars with the crossed patterns, APTMS-functionalized PDMS is shown in bars with the straight patterns, and plastic is shown in bars with the square patterns.

Evidence of substrate functionalization

In order to provide evidence of successful substrate functionalization we utilized the fact that a His-tagged GFP protein selectively binds to the active groups available through the APTMS or PEIGA functionalization, while not binding to the hydroxyl groups present on the bare PDMS unfunctionalized surface.

We incubated both bare unfunctionalized PDMS and APTMS and PEIGA functionalized PDMS with the His-tagged GFP and subsequently measured the fluorescent intensity over the samples, while subtracting the auto-fluorescent background of the PDMS without the GFP protein. Supplementary Figure 2 shows that the fluorescent intensity of GFP is higher on both functionalized substrates indicating that successful functionalization was achieved.

Supplementary Figure 2. Characterization of functionalization through His-tagged GFP binding. The plotted lines illustrates the fluorescent intensity of the GFP protein as measured in a line over the samples, when the auto-fluorescent background of PDMS has been subtracted.

Selection of adhesion supportive laminins

The ability to support cell adhesion and growth among a selection of laminins was assessed (Supplementary Figure 3). Human recombinant Laminins 111, 211, 221, 411, 421, and 511 were tested. On day after monolayer seeding both attachment and cell spreading can be seen on Laminins 111, 411, 421, and 511. Five days after seeding some attachment is seen on Laminins 111, 411, and 421, while on Laminin 511 there is a $\approx 75\%$ confluent monolayer.

Supplementary Figure 3. Evaluation of intestinal epithelial cell adhesion to different laminins at day 1 and 5 after seeding. The image in the dashed square shows a magnification. At day 1 attachment and cell spreading is seen on laminins 111, 411, 421, and 511. At day 5 some attachment is seen on laminins 111, 411, and 421, while on laminin 511 there is a $\approx 75\%$ confluent monolayer.

Supplementary Figure 4. Evaluation of intestinal epithelial cell growth on PDMS without coating at day 6 on PEIGA, plastic, APTMS and PDMS. A) Cells cultured in ENR medium. B) Cells cultured in CV medium (nuclei blue, actin green). In both cases, no adhesion was seen. Scale bar 200 μ m.

Different medium compositions impact the small intestine organoid morphology

Supplementary Figure 5 compares brightfield images of murine small intestinal organoids in both CV and ENR media at day 7. In presence of CV, the organoids tend to stay round and do not bud (Supplementary Figure 5A), while if cultured in ENR, the morphology is more irregular, with a consistent presence of buds (Supplementary Figure 5B).

Supplementary Figure 5. Brightfield microscope images of murine intestinal organoids in different cell culture media at day 7. A) CV medium in and B) ENR medium.
