## 1. Experimental Procedures

### 1.1 Materials

All chemicals and reagents were obtained from Carl Roth (Karlsruhe, Germany), Sigma-Aldrich (St. Louis, MO, USA), Alfa Aesar (Haverhill, MA, USA), Biomol (Hamburg, Germany) and Fisher Scientific (Hampton, NH, USA). Primers, enzymes and additional material used for molecular cloning were purchased either from New England Biolabs (NEB), Thermo Fisher Scientific or Sigma-Aldrich. Custom synthesized DNA was obtained from Biocat (Heidelberg, Germany) and Twist Bioscience (South San Francisco, CA, USA). DNA sequencing was carried out by Eurofins Genomics (Ebersberg, Germany) and Microsynth (Balgach, Switzerland). For protein purification, equipment (MBP-Trap columns, Ni-NTA-columns and gelfiltration columns) from Cytiva (Marlborough, MA, USA) was used. Concentration of proteins was carried out in centrifugal devices from Thermo Fisher Scientific and PALL (New York, USA). SDS-PAGE and Agarose gel electrophoresis were carried out in equipment from Cleaver Scientific (Rugby, UK).

### 1.2 Media and Microorganisms

Since the strain *Streptomyces cyaneofuscatus* Soc7 was unobtainable, 3,7-dihydroxytropolone formation was investigated in two strains with homologous gene clusters, i.e. *Longimycelium tulufanense* DSM 46696 and *Amycolatopsis regifaucium* DSM 45072 (both obtained from the German Collection of Microorganisms and Cell Cultures, DSMZ). The media used to cultivate both strains on plates was GYM Streptomyces medium (D-glucose 4 g/L, yeast extract 4 g/L, malt extract 10 g/L, CaCO<sub>3</sub> 2 g/L and agar 12 g/L). For cultivation in liquid media either GYM Streptomyces medium (D-glucose 4 g/L, yeast extract 4 g/L, malt extract 10 g/L and CaCO<sub>3</sub> 2 g/L) or GYM-NaCl medium (D-glucose 4 g/L, yeast extract 4 g/L, malt extract 10 g/L, NaCl 4 g/L and CaCO<sub>3</sub> 2 g/L) was used. Both strains were cultivated at 140 rpm, *Longimycelium tulufanense* at 37°C and *Amycolatopsis regifaucium* at 28°C.

### 1.3 Cloning and recombinant production of TrIA

For the recombinant production of TrIA (NCBI accession number: AWF83805.1, see table S1) the corresponding gene was synthesized and codon optimized for *E. coli* by Biocat. Restriction digestion of the gene was carried out with NotI (3') and NcoI (5'), afterwards the gene was cloned into the pET-M11-His-gb1-TEV vector. This vector contained the solubility enhancer protein gb1 (B1 domain of *Streptococcal* protein g) between the hexahistidine-tag and the tobacco etch virus (TEV)-cleavage site at the N-terminus of the protein. After proper insertion into the target vector was confirmed by sanger sequencing, the corresponding plasmid was transformed into *E. coli* BL21 (DE3) pL1SL2 cells obtained from Leadley et al.<sup>1</sup> These cells contain the GroES/GroEL chaperonin system from *Streptomyces coelicolor*, which facilitate correct folding of proteins from G+C rich species. Gene expression was carried out in TB-medium supplemented with kanamycin (50 µg/mL), ampicillin 100 µg/mL, chloramphenicol (20 µg/mL) and D-glucose (0.2% w/v). For inoculation, a pre-culture was grown in LB-medium (supplemented with the same amount of antibiotics and glucose) until an OD<sub>600</sub> of ~0.1 was reached. The main culture was incubated at 37°C and 130 rpm until an OD<sub>600</sub> of ~0.6 was reached. Afterwards, the temperature was adjusted to 18°C and protein production was induced with 0.25 mM IPTG. The cells were harvested after overnight incubation at 5.000 x g, washed with 0.9 % NaCl solution (w/v), centrifuged again at 5.000 x g and then frozen at -20°C.

#### **1.4 Protein purification of TrIA**

The cells were resuspended in buffer with 10 % glycerol (v/v), 300 mM NaCl, 50 mM sodium phosphate buffer (Na<sub>2</sub>HPO<sub>4</sub>/ NaH<sub>2</sub>PO<sub>4</sub>) at pH 7.4 (buffer A). After 15 min incubation on ice, the cells were lysed by ultrasonication (3 s pulse, 3 s pause; 4 min pulse time, amplitude: 60 %, 2 times). The lysate was centrifuged for 30 min at 18.000 x g to remove cell debris. The remaining supernatant was then filtered through a PVDF filter with pore size of 0.22 µm before being loaded on a Ni-NTA column (Cytiva) equilibrated with buffer A. Unspecific bound proteins were eluted by washing with 10 column volumes of buffer A and buffer B with a ratio of 96:4 (buffer B consists of buffer A + 500 mM imidazole). The His-gb1-tagged protein was eluted using 100 % buffer B. Small samples (20 µL) from each elution fraction were taken for SDS-PAGE analysis (see Figure S37), fractions containing the desired protein were pooled together and concentrated in an Amicon centrifugal filter (Sigma Aldrich). Subsequently, the buffer was exchanged using a desalting column (HiTrap Desalt, Cytiva), the obtained fractions concentrated and flash frozen in liquid nitrogen before being stored at -80°C.

#### **1.5 Cloning, recombinant production and protein purification of TrIC**

The procedure for cloning, recombinant production and purification of TrIC (NCBI accession number: AWF83807.1, see table S1), was carried out the same way as for TrIA. Only exception was using a vector with different tags for cloning, namely the pET-M11-His-TEV vector (for SDS-PAGE analysis see Figure S38).

#### **1.6 Cloning, recombinant production and protein purification of TrID**

The procedure for cloning, recombinant production and purification of TrID (NCBI accession number: AWF83808.1, see table S1), was carried out the same way as for TrIA (for SDS-PAGE analysis see Figure S39).

#### **1.7 Cloning, recombinant production and protein purification of TrIE**

The procedure for cloning, recombinant production and purification of TrIE (NCBI accession number: AWF83809.1, see table S1), was carried out the same way as for TrIA. Only differences were adding a spatula tip of FAD to the resuspended cells prior to sonication and supplementing buffer A and B during purification with 10 µM of FAD (for SDS-PAGE analysis see Figure S40).

#### **1.8 Cloning, recombinant production and protein purification of TrIF**

The procedure for cloning and recombinant production of TrIF (NCBI accession number: AWF83810.1, see Table S1), was carried out the same way as for TrIA. Only exception was using a vector with different tags for cloning, namely the pET-M11-MBP-TEV vector, containing a solubility enhancer protein MBP (Maltose binding protein) in front of the tobacco etch virus (TEV)-cleavage site at the N-terminus of the protein.

For protein purification the buffers and FPLC program were altered to suit the new MBP-tag. Buffer A contained 10 % glycerol (v/v), 200 mM KCl, 20 mM Tris, at pH 8 (buffer A) and buffer B contained 10 % glycerol (v/v), 200 mM KCl and 10 mM Maltose at pH 8. Elution was carried out using a linear gradient of B 0 % to 100 % buffer B within 10 column volumes) (for SDS-PAGE analysis see Figure S41).

#### **1.9 Cloning, recombinant production and protein purification of TrIE Variants**

Genes encoding variants of TrIE (amino acid exchange either, H213A, H213E, H213Q or Y217H) were obtained from TwistBioScience in a pET28a vector, which allowed for production of heterologous proteins with an N-terminal hexahistidine-tag followed by a gb1-tag and the tobacco etch virus (TEV)-cleavage site. The whole construct was flanked by NcoI and XhoI cleavage sites. Recombinant production and protein purification were carried out as described for TrIE (for SDS-PAGE analysis see Figures S42 - 45).

### 1.10 Recombinant production and purification of PaaABCE, PaaG, PaaZ-E256Q and PaaY

Recombinant production and purification of PaaABCE, PaaG, PaaZ-E256Q and PaaY were carried out as previously described.<sup>2-4</sup>

### 1.11 Multiple sequence alignment TrIE gene cluster

A pBLAST was conducted with the sequence of TrIE from *Streptomyces cyaneofuscatus* Soc7 against the non-redundant protein sequences database from NCBI. The genomic environments of the putative *trIE* genes were scrutinized for other potential *trI* genes and newly identified gene clusters were then included in the multiple sequence alignment. Chosen sequences were aligned and visualized using the software CAGECAT<sup>5</sup>.

### 1.12 Phylogenetic distance tree TrIE

Amino acid sequences of TrIE and known FAD-dependent group A monooxygenases with solved crystal structure were aligned using the ClustalW algorithm with default settings. The alignment was processed and visualized with the software Mega11<sup>6</sup> using the Jones-Taylor-Thornton (JTT) matrix based model and maximum likelihood method (1,000 replicates) (for PDB codes see Table S2).

### 1.13 Analytical size exclusion chromatography (SEC)

Analytical size exclusion chromatography was carried out using a Superdex 200 GL 10/300 column (Cytiva). The column was equilibrated with 10% glycerol, 300 mM NaCl, 50 mM sodium phosphate buffer (Na<sub>2</sub>HPO<sub>4</sub>/ NaH<sub>2</sub>PO<sub>4</sub>) at pH 7.4 for all his-tagged protein and 10 % glycerol, 20 mM Tris, 200 mM KCl at pH 8 for all MBP-tagged proteins. Proteins were run at 0.4 mL/min and molecular weights of the eluting main peaks were estimated from a previously generated calibration curve with proteins of known molecular weight (see Figure S46).

### 1.14 Determination of melting temperature (TM) of TrIE and variants

The melting temperatures of TrIE and its variants were determined using the Prometheus NanoDSF device from NanoTemper Technologies. Protein concentration was adjusted to 5 μM in 50 mM Tris-HCl buffer with pH 8. Possible binding partners were added to a final concentration of 1 mM. All measurements were performed in triplicates. Samples were equilibrated at 20°C prior to measurement start. During measurement the temperature increased for 1.5°C per minute until 95°C was reached.

### 1.15 Crystallization of TrIE, data collection and refinement

TrIE (8.8 mg/mL in 50 mM Tris pH 7.4, 10% glycerol and 250 μM FAD) was crystallized at room temperature using sitting-drop vapor diffusion method by mixing 300 nL of protein with 300 nL of precipitant (0.1 M Bis-Tris propane pH 8.5, 0.25 M Na<sub>2</sub>SO<sub>4</sub>, 15 % (w/v) PEG 3350). Small rods appeared after 13 days and grew in size for additional 20 days.

Data was collected at the SLS beamline X06SA (Swiss Light Source, Paul Scherrer Institute, Switzerland) at 100 K and were processed using XDS software<sup>7</sup> and scaled using aimless<sup>8</sup>. The crystal structure was determined by molecular replacement with Phaser<sup>9</sup> using an AlphaFold-model<sup>10</sup> of TrIE. Manual model building was done with Coot<sup>11</sup> and structure refinement in PHENIX<sup>12</sup> and REFMAC5<sup>13</sup>. Model quality was validated with Molprobit<sup>14</sup>. Data collection and refinement statistics are summarized in Table S3. The atomic coordinates and structure factors have been deposited in the Protein Data Bank under the accession code 8RQH.

### 1.16 Docking, molecular dynamics (MD) simulation and energy minimization

Dihydrotropone-2-carboxylate (**7**) was docked into the obtained crystal structure of TrIE using Induced Fit Docking protocol<sup>[13,14]</sup>. Compound **7** and the protein structure were prepared with standard settings using LigPrep (LigPrep, Schrödinger, LLC, New York, NY, 2024) and Protein Preparation Wizard<sup>[15]</sup>, respectively. To define the search volume for docking, the homologous structure of salicylate hydroxylase with co-crystallized 2-hydroxybenzoic acid was first aligned to the crystal structure of TrIE.

The search volume was defined based on the position of 2-hydroxybenzoic acid in the superimposed structure.

Based on the top-ranked docking pose, molecular dynamics simulation was performed using Desmond<sup>[16]</sup> in an NPT-ensemble using OPLS2005 force field. Periodic boundary conditions were applied to the protein-ligand system in a cubic water box with a 10 Å water buffer around the protein. Electrostatic forces were treated using particle-mesh Ewald summation with a short range cut-off of 9 Å. After the default relaxation protocol, MD simulation was performed for 100 ns with frames stored every 100 ps. The MD trajectory was clustered and the representative structure of the largest cluster minimized using simulated annealing for 100 ps. The final structure was utilized for visual analysis and interpretation.

### **1.17 Chemical synthesis of phenylacetyl-CoA (PaCoA) (1)**

Phenylacetyl-CoA was synthesized using phenylacetyl succinimide and coenzyme A as described in literature.<sup>2, 15</sup> Purification was carried out by means of preparative HPLC. The sample was filtered and applied to a Sunfire Prep C18 column (10x150 mm, Waters Corporation) equilibrated with 2 % acetonitrile and 98 % 10 mM ammonium acetate buffer (pH 4.5). The sample was eluted with a flow rate of 4 mL/min and absorption was monitored at 260 nm with an UV diode array detector. After collection, the sample was lyophilized and subsequently stored at -80°C upon further usage.

### **1.18 HPLC analysis**

Assay analysis by HPLC was carried out on an Agilent 1100 chromatographic system, equipped with a SemiPrep VP NUCLEODUR Gravity SB column (250 x 10 mm ID, 5 µm, Macherey-Nagel) combined with a UNIVERSAL RP guard column (4 x 3 mm ID, Macherey-Nagel). Pre-equilibration of the column was conducted with either 10 mM AmAc pH 4.5 (solution A1) and acetonitrile (solution B1) in a ratio of 98:2 for analysis of aqueous samples or with H<sub>2</sub>O + 0.1 % formic acid (solution A2) and acetonitrile + 0.1 % formic acid (solution B2) in a ratio of 98:2 for extracted compounds. The flow rate was set to 3 mL/min with following gradient: 2 % - 60 % B1/2 (0 - 15 min), 60 % B1/2 (15 - 16 min), 60 % - 2 % B1/2 (16 - 17 min), 2 % B1/2 (17 - 25 min). Absorption was monitored at 260, 300 and 340 nm by the DAD-detector. Purification of compounds from upscaled assays and cell cultures was performed on an Agilent 1100 chromatographic system equipped with an XBridge BEH C18 OBD Prep column (150 x 10 mm ID, 5 µm, Waters) equipped with a guard column. Pre-equilibration of the column was conducted using H<sub>2</sub>O + 0.1 % formic acid (solution A2) and acetonitrile + 0.1 % formic acid (solution B2) in a ratio of 95:5. The flow rate was set to 4 mL/min with following gradient: 5 % B2 (0 - 2 min), 5 % - 12 % B2 (2 - 7 min), 12 % B2 (7 - 9 min), 12 % - 60 % B2 (9 - 17 min), 60 % B2 (17 - 23 min), 60 % - 100 % B2 (23 - 24 min), 100 % B2 (24 - 27 min), 100 % - 5 % B2 (27 - 28 min), 5 % B2 (28 - 33 min). Absorption was monitored at 260, 280, 300, 350 and 370 nm as all of these wavelengths were maxima of different compounds occurring in the enzymatic assays.

### **1.19 LC-HRMS and LC-MS analysis**

LC-HRMS and LC-MS analysis of assays was carried out on two different systems. The system used for LC-HRMS was a Waters Acquity UPLC H class system coupled with a diode array detector. For LC-MS analysis a Shimadzu LCMS-8030 Triple Quad Mass Spectrometer was used, equipped with an analytical SunFire C18 column (150 x 3 mm ID, 3.5 µm, Waters) combined with a guard column (10 x 3 mm ID). Pre-equilibration of the column was conducted with either 10 mM AmAc pH 4.5 (solution A1) and acetonitrile (solution B1) in a ratio of 98:2 for analysis of aqueous samples or with H<sub>2</sub>O + 0.1 % formic acid (solution A2) and acetonitrile + 0.1 % formic acid (solution B2) in a ratio of 98:2 for extracted compounds. The flow rate was set to 0.4 mL/min with following gradient: 2 % - 12 % B1/2 (0 - 4 min), 12 % B2 (4 - 6 min), 12 % - 60 % B1/2 (6 - 14 min), 60 % B1/2 (14 - 18 min), 60 % - 100 % B1/2 (18 - 19 min), 100 % B1/2 (19 - 24 min), 100 % - 2 % B1/2 (24 - 25 min), 2 % B1/2 (25 - 30 min). Absorption

was monitored from 190 – 800 nm. Samples were analyzed in MS ESI positive and negative mode with a capillary voltage of 3 kV, 250°C DL temperature, 400 °C heat block temperature and 3 L/min nebulizing gas flow.

### **1.20 Enzymatic synthesis of 2**

In order to produce **2**, an assay containing 0.5 mM PaCoA (**1**), 1 mg/mL PaaABCE and 1  $\mu$ M PaaG was prepared in 50 mM Tris-HCl pH 8 buffer and incubated at 30°C for 2 minutes. Afterwards, 1.5 mM of NADPH was added to start the reaction. The assay was incubated at 30°C and 900 rpm for 10 min and stopped with methanol. The sample was lyophilized overnight and subsequently resuspended in water. Purification was carried out by means of preparative HPLC. The sample was filtered and applied to a SemiPrep VP NUCLEODUR Gravity SB column (250 x 10 mm ID, 5  $\mu$ m, Macherey-Nagel) combined with a UNIVERSAL RP guard column (4 x 3 mm ID, Macherey-Nagel) and equilibrated with 2 % acetonitrile and 98 % 10 mM ammonium acetate buffer (pH 4.5). The sample was eluted with a flow rate of 3 mL/min and absorption was monitored at 260 nm with an UV diode array detector. After collection, the sample was lyophilized and subsequently stored at -80°C upon further usage.

### **1.21 Enzymatic synthesis of 3**

In order to produce **3**, an assay containing 0.5 mM PaCoA (**1**), 1 mg/mL PaaABCE, 1  $\mu$ M PaaG and 1.5  $\mu$ M PaaZ-E256Q was prepared in 50 mM Tris-HCl pH 8 buffer and incubated at 30°C for 2 minutes. Afterwards, 1.5 mM of NADPH (**1**) was added to start the reaction. The assay was incubated at 30°C and 900 rpm for 10 min. The resulting substrate mix was then used in subsequent assays.

### **1.22 Turnover assay with TrIF**

To investigate the enzymatic function of TrIF, 350  $\mu$ L of the substrate mix (described in production of **3**) was prepared freshly. 50  $\mu$ L were set aside and quenched with an equal amount of ethyl acetate + 1 % formic acid serving as the control sample. The other 300  $\mu$ L were incubated with 2.5  $\mu$ M TrIF at 30°C and 900 rpm. Samples with 50  $\mu$ L each were taken after 0, 2, 4, 6, 8 and 10 min and quenched with an equal amount of ethyl acetate + 1 % formic acid. Following this, all samples were centrifuged for 10 min at 18.000 x g. The ethyl acetate fractions were dried in a speed-vac for 1 h and resuspended in 50  $\mu$ L of acetonitrile before being analyzed by HPLC-DAD and LC-MS.

### **1.23 Carbonic Anhydrase Test**

Carbonic anhydrase activity of TrIF was tested in assays measured on a plate reader MultiSkan Go (ThermoScientific) using the pH indicator dye phenol red. In 60  $\mu$ L of 20 mM Tris-HCl pH 8 buffer and 40  $\mu$ L of CO<sub>2</sub>-saturated water phenol red is added to a final concentration of 5  $\mu$ M. The CO<sub>2</sub>-saturated water was prepared by putting dry ice into distilled and deionized water and letting it dissolve for 30 min. The reaction was started by adding different amounts of TrIF to the solution. Controls were analyzed without the addition of any protein. After reaction start the OD557nm was measured every second. All measurements were performed in triplicates.

### **1.24 Turnover assay with TrIE**

To investigate the enzymatic function of TrIE, 400  $\mu$ L of the turnover assay with TrIF were prepared freshly and incubated for 10 min at 30°C and 900 rpm. Then, TrIE and NADPH were added to a final concentration of 0.1  $\mu$ M and 1.5 mM respectively. The assay was incubated at 30°C and 900 rpm. Samples with 50  $\mu$ L each were taken after 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5 and 4 min and quenched with an equal amount of ethyl acetate + 1 % formic acid. Subsequently, all samples were centrifuged for 10 min at 18.000 x g. The ethyl acetate fractions were dried in a speed-vac for 1 h and resuspended in 50  $\mu$ L of acetonitrile before being analyzed by HPLC-DAD and LC-MS.

### 1.25 Tropone turnover assay with TrIE

To rule out the possibility of tropone being the native substrate for TrIE, an assay containing 0.5 mM of tropone (commercially available standard, Alfa Aesar) and 2.5  $\mu$ M TrIE and 1.5 mM NADPH in 100  $\mu$ L Tris-HCl pH 8 was conducted. The reaction mixture was incubated at 30°C and 900 rpm for 10 min and subsequently quenched with an equal amount of ethyl acetate + 1 % formic acid. The sample was dried in a speed-vac for 1 h and resuspended in 100  $\mu$ L of acetonitrile before being analyzed by HPLC-DAD.

### 1.26 Turnover assay with TrICD

In order to assess the function of the two component flavoprotein monooxygenase TrICD, an assay containing tropolone and a NADH regeneration system was conducted. The reaction mixture contained 25  $\mu$ M TrIC, 125  $\mu$ M TrID, 100  $\mu$ M sodium formate, 4 U/mL formate dehydrogenase, 0.1 mg/mL catalase, 30  $\mu$ M FAD, 5 mM NADH and 0.5 mM tropolone in Tris-HCl pH 8. The assay was incubated at 30°C and 900 rpm. 50  $\mu$ L samples were taken at 0, 0.5, 1, 2, 3, and 4 hours and quenched with an equal volume of ethyl acetate + 1 % formic acid. The samples were centrifuged at 18.000 x g and the ethyl acetate fractions were subsequently dried under N<sub>2</sub> gas flow. Samples were resuspended in a 4:1 mixture of water and acetonitrile containing 50 mM of EDTA before being analyzed by HPLC-DAD and LC-MS. The assay was also conducted with a substrate mix containing enzymatically produced tropolone (as described in the turnover assay with TrIE) as a control. Since there were no observable changes in the outcome of the assay, commercially available tropolone was used hereafter to reduce assay complexity.

### 1.27 Comparison of TrIA and PaaZ-E256Q

To investigate the possible hydratase function of TrIA in comparison to PaaZ-E256Q, assays were conducted containing 0.5 mM PaCoA (**1**), 1 mg/mL PaaABCE, 1  $\mu$ M PaaG and 1.5  $\mu$ M of either PaaZ-E256Q or TrIA, respectively, which were incubated in 50 mM Tris-HCl pH 8 buffer at 30°C for 2 minutes. Afterwards, 1.5 mM of NADPH was added to start the reaction. After 15 min the reaction was stopped with an equal volume of methanol. The samples were vortexed, centrifuged at 18.000 x g and subsequently dried for 30 min in a speed-vac before being analyzed by HPLC.

### 1.28 Oxepin-CoA assay TrIE

To assess the necessity of NADPH for tropolone formation by TrIE, an assay using oxepin-CoA as starting substrate was prepared. 1 mM of oxepin-CoA was incubated with 1.5  $\mu$ M of PaaZ-E256Q at 30°C and 900 rpm for 10 min. Subsequently, 2.5  $\mu$ M TrIF was added and the assay was incubated for another 10 min with the same conditions. Afterwards, the reaction mixture was split into two equal parts. 2.5  $\mu$ M TrIE was added to one of the assays. Both reaction mixtures, with and without TrIE, were incubated for an additional 10 min at 30°C and 900 rpm. The assays were stopped with an equal volume of ethylacetate + 1 % formic acid, vortexed and centrifuged at 18.000 x g. Samples were dried in a speed-vac for 30 min, volumes were adjusted to 50  $\mu$ L with acetonitrile, before being analyzed by HPLC.

### 1.29 <sup>18</sup>O<sub>2</sub>-labeling assays

To study oxygen incorporation of O<sub>2</sub> into tropolone, assays were conducted with <sup>18</sup>O labeled oxygen. **3** was produced by mixing 250  $\mu$ M of oxepin-CoA with 5  $\mu$ M of PaaZ-E256Q in an anoxic environment (glove box) in Tris-HCl pH 8 and the mixture then incubated for 10 min at RT. Afterwards, TrIF was added to a final concentration of 2.5  $\mu$ M and incubated for another 10 min at RT. TrIE was added to a final concentration of 2.5  $\mu$ M to the assay, then the reaction mixture was split into two equal parts. Both reaction mixtures were transferred to an anaerobic air-tight bottle with septum. Upon removal from the glove box ~2 ml of <sup>18</sup>O<sub>2</sub> was injected into one of the bottles, the other was opened. Both reaction mixtures were incubated at 30°C and 900 rpm for 15 min, then ethylacetate + 1 % formic acid was added to stop the reaction and extract the reaction products. Samples were vortexed and

centrifuged at 18.000 x g afterwards. Subsequently, the samples were dried in the speed-vac for ~30 min, the volume was adjusted to 50  $\mu$ L using acetonitrile, before analyzing  $^{18}\text{O}$  incorporation on the LC-HRMS system.

### 1.30 Differential scanning fluorimetry (DSF) measurements

In order to determine the melting point of all produced proteins DSF measurements were carried out on a NanoDSF Prometheus from NanoTemper Technologies (Munich, Germany). Protein concentrations were adjusted to 10  $\mu$ M in degassed 50 mM Tris-HCl buffer with pH 8. Ligands were dissolved in the same buffer and as concentration 50  $\mu$ M for FAD and 1 mM for salicylate was used as final concentrations. The temperature increase was set to 1.5°C per minute and the overall temperature gradient was set from 25°C to 90°C. All measurements were performed in triplicates.

### 1.31 Re-oxidation of **4**

To investigate the proposed ring oxidation step by TrIE in the course of **4** synthesis, a re-oxidation assay was conducted in which 25  $\mu$ M of **4** in Tris-HCl pH 8 was first reduced using 200  $\mu$ M of sodium dithionite. This chemical reduction in aqueous solution could be followed by monitoring the absorption at 340 nm using a NanoPhotometer NP80 device (Implen), which subsequently also allowed to determine the rate of re-oxidation to **4** for different concentrations of TrIE (0.5, 1 and 2  $\mu$ M). As controls, heat-denatured TrIE with the same concentrations (0.5, 1 and 2  $\mu$ M) as well as pure FAD (2  $\mu$ M) were used. All measurements were performed with n = 4.

### 1.32 Cultivation of *Longimycelium tulufanense*

*L. tulufanense* was cultivated on GYM Streptomyces medium agar plates (D-glucose 4 g/L, yeast extract 4 g/L, malt extract 10 g/L,  $\text{CaCO}_3$  2 g/L and agar 12 g/L). A single colony was picked from the agar plate after 5 days of cultivation and incubated in 50 mL GYM-NaCl medium (D-glucose 4 g/L, yeast extract 4 g/L, malt extract 10 g/L, NaCl 4 g/L and  $\text{CaCO}_3$  2 g/L) at 140 rpm and 37°C for 5 days. The culture was harvested by centrifugation at 18.000 x g for 30 min, the supernatant as well as the pellet fraction were extracted with EtOAc + 1 % FA. The extracts were dried under  $\text{N}_2$  gas flow and resuspended in a 4:1 mixture of water and acetonitrile containing 50 mM of EDTA before being analyzed by HPLC-DAD and LC-MS.

### 1.33 NMR measurement of **5**

Compound **5** was obtained from an upscaled enzymatic reaction (20 mL) described under 1.25. The reaction mixture was extracted two times with an equal amount of EtOAc + 1 % FA. The combined organic phases were dried using  $\text{N}_2$  and the dried residue was purified using semi-preparative HPLC collecting the peak containing compound **5** (see 1.18). Fractions containing isolated **5** were extracted two times with an equal amount of EtOAc + 1 % FA, the organic phases combined and dried under  $\text{N}_2$  gas flow and subsequently stored at -80°C until NMR measurement.

NMR samples were dissolved in 120  $\mu$ L of deuterated benzene ( $\text{C}_6\text{D}_6$ ) and transferred into 3 mm NMR tubes. Spectra were measured on a Bruker Avance III NMR spectrometer operating at 500.13 MHz for  $^1\text{H}$  and 125.77 MHz for  $^{13}\text{C}$  nuclei.  $^1\text{H}$ ,  $^{13}\text{C}$ , COSY, HSQC, and HMBC spectra were recorded at 23°C on a BBO probe.

Compound **5**:  $^1\text{H}$  NMR (500 MHz,  $\text{C}_6\text{D}_6$ )  $\delta$  ppm 6.24 (m, H-4/5)  $\delta$  ppm 6.97 (m, H-3/6),  $^{13}\text{C}$  NMR (126 MHz,  $\text{C}_6\text{D}_6$ )  $\delta$  ppm 120.4 (C-3/6) 129.3 (C-4/5) 160.1 (C-2/7) 169.8 (C-1).

## 2. Supplemental Figures and Tables:

Table S1 Trl gene cluster of *Streptomyces cyaneofuscatus* Soc7

Trl gene cluster	Annotation	AA	
<b>TrIA</b>	AWF83805.1	Enoyl hydratase	159
<b>TrIB</b>	AWF83806.1	DAHP synthase	484
<b>TrIC</b>	AWF83807.1	Tropolone 3,7-monooxygenase oxidase component	530
<b>TrID</b>	AWF83808.1	Tropolone 3,7-monooxygenase flavin reductase component	185
<b>TrIE</b>	AWF83809.1	Tropone 2-monooxygenase	400
<b>TrIF</b>	AWF83810.1	1,4,6-cycloheptatriene-1-carboxylic acid decarboxylase	203
<b>TrIG</b>	AWF83811.1	putative A-factor biosynthesis hotdog domain-containing protein	253
<b>TrIH</b>	AWF83812.1	Bifunctional prephenate dehydratase and chorismate mutase	402
<b>TrII</b>	AWF83813.1	TetR family transcriptional regulator	209

**Figure S1 Observed production of 4, 5, and 6 in *Longimycelium tulufanense*.** After 5 days of incubation of *Longimycelium tulufanense* in GYM-NaCl media at 37°C and 140 rpm, the three distinct (hydroxyl)tropolones 4, 5 and 6 could be observed in the supernatant as well as in the pellet fraction of harvested cultures. Shown are the UV traces from RP-HPLC (300 nm) and the extracted ion chromatograms (EIC) with corresponding masses in the ionization modes which gave the best signals (positive mode for 4 and 5, negative mode for 6, all ESI). Retention time, UV-visible spectra and masses measured on the LCMS system matched the data obtained in the *in vitro* assay with the *Trl* enzymes. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

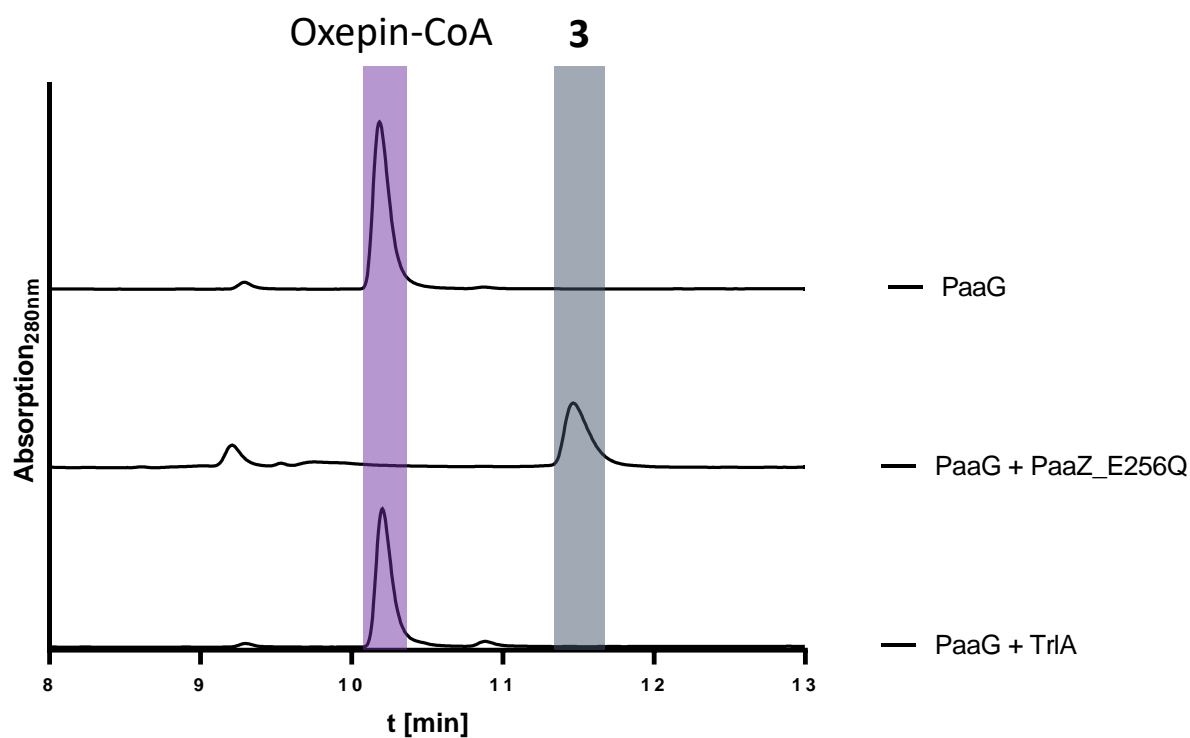

Figure S2 UV-visible spectra of compounds 4, 5 and 6

**Figure S3 Functional test of putative hydratase TrIA.** No visible conversion of the substrate oxepin-CoA (produced by PaaG) was observed in the assay when TrIA was added. When the enoyl-CoA hydratase variant PaaZ-E256Q was added full conversion of oxepin-CoA to 3 was observable. Samples were measured with the HPLC program for the semiprep nucleodur column (see above in method section, 1.18 HPLC analysis).

**Figure S4 Multiple sequence alignment of TrlA from *Streptomyces cyaneofuscatus* Soc7, PaaZ from *E. coli* K12 and homologue proteins from other organisms.** Catalytically important residues are highlighted in red. The alignment was generated with ClustalOmega using the default parameter settings.

**Figure S5 Time course of 7 formation by TrIF (A)** RP-HPLC chromatograms at 300 nm showing the time course of the formation of 7 (from 3, which is not shown here, as the polar CoA esters were not extracted by organic solvents), highlighted in blue. Small amounts of tropone (8) could be observed after prolonged incubation time (highlighted in green). **(B)** Relative amounts of 7 (as determined by the area under each peak) produced by TrIF in A. **(C)** Mass spectrum of 7 in negative ion mode. Samples were measured with the HPLC program for the semiprep nucleodur column (see above in method section, 1.18 HPLC analysis).

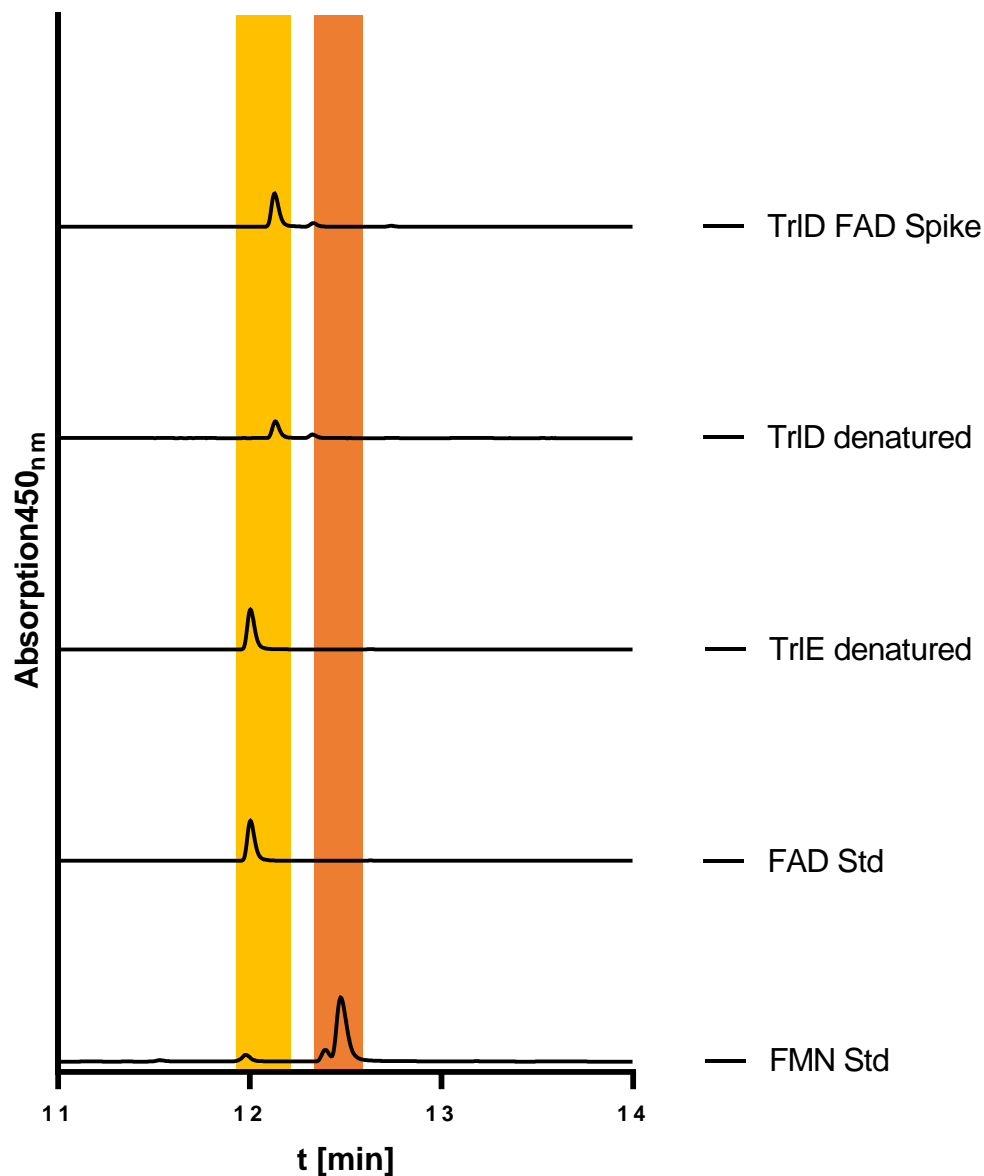

**Figure S6 Oxidation of 7 to tropone-2-carboxylate (verified by chemically synthesized standard).** 1 mM of potassium ferricyanide (III) was incubated with 7 for 5 min at 30°C and analyzed subsequently by RP-HPLC. Oxidation product was compared to a chemically synthesized standard and exhibited the same retention time and UV-visible spectrum. Samples were measured with the HPLC program for the semiprep nucleodur column (see above in method section, 1.18 HPLC analysis).

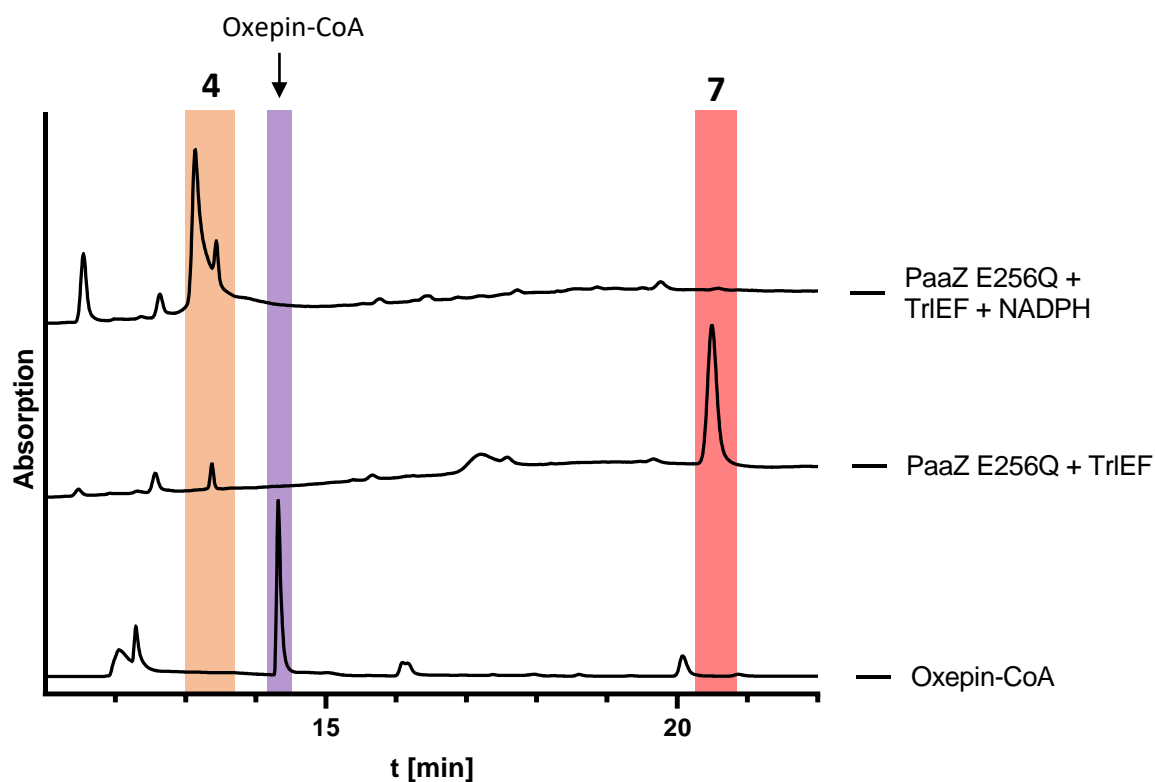

**Figure S7 Multiple sequence alignment of TrlF from *Streptomyces cyaneofuscatus* Soc7 and homologues from other organisms.** PaaY represents the phenylacetic acid degradation protein PaaY, CA represents carbonic anhydrase functionality. Residues expected to be important for the trimeric interface are highlighted in red, residues expected to be important for metal binding (most likely Zn<sup>2+</sup>) are highlighted in light blue. The alignment was generated with ClustalOmega, using the default parameter settings.

**Figure S8 Test for carbonic anhydrase activity of TrIF.** Two different concentrations of TrIF (blue: 45  $\mu\text{M}$ , red: 17.5  $\mu\text{M}$ ) were incubated with the pH indicator dye phenol red in 20 mM Tris-HCl pH 8 buffer and  $\text{CO}_2$ -saturated water. The control group was incubated without any enzyme (black). Changes of the  $\text{OD}_{557\text{nm}}$  were monitored over time. All samples were prepared in triplicates.

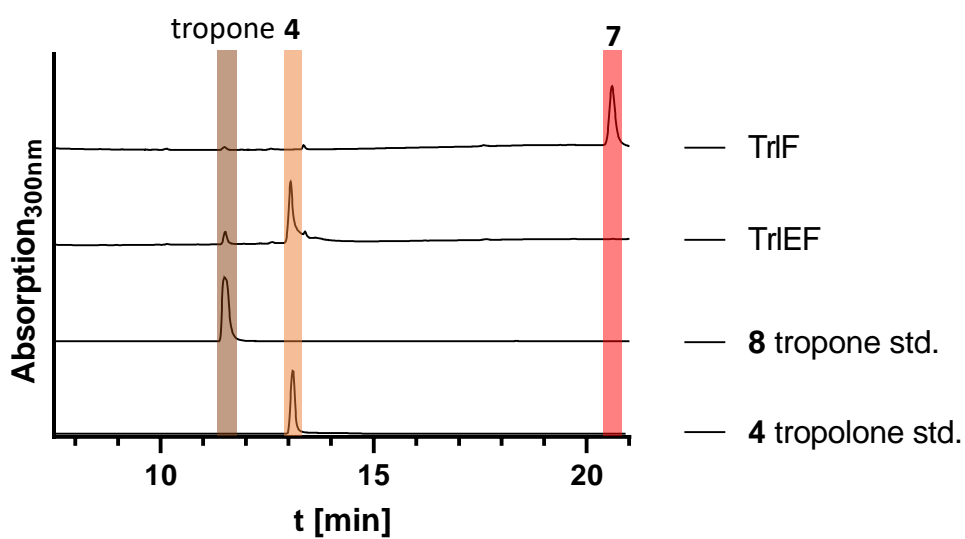

**Figure S9 RP-HPLC analysis (450 nm) of isolated cofactors from TrIE and TrID.** Enzymes were heated at 95°C for 10 min, centrifuged for 10 min at 13.000 x g and the supernatant applied to the HPLC. Retention time of the cofactor was compared to commercially available standards. The slight shift in retention time for TrID was due to some protein aggregates still being in the supernatant (peak observable at 280 nm). Spiking with FAD increased the cofactor peak, indicating FAD as the correct cofactor. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

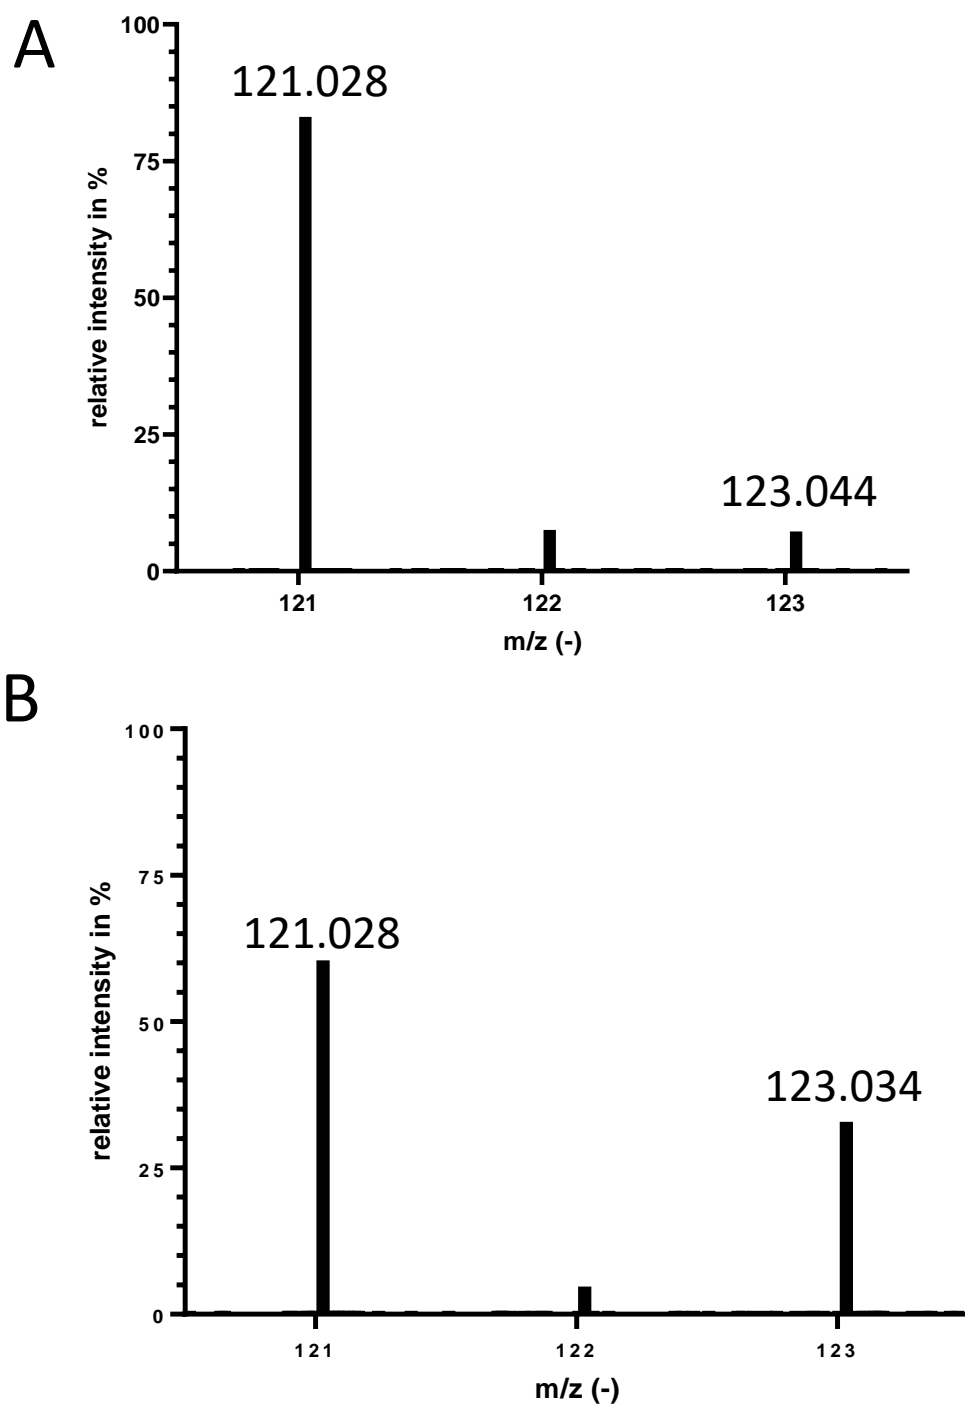

**Figure S10 NADPH-dependency of the turnover of (TrIF-produced) 7 to tropolone (4) by TrIE.** To investigate the need for NADPH as a cofactor for TrIE, oxepin-CoA was collected and used as a substrate in an assay with PaaZ E256Q, TrIF and TrIE. If no NADPH was added, only the formation of 7 by TrIF was observable. When NADPH was added to the assay, 4 was produced by TrIE. All samples were measured on a RP-HPLC system (see above in method section, 1.18 HPLC analysis), absorption was monitored at 280 nm (oxepin-CoA, highlighted in lila) and 300 nm (PaaZ E256Q + TrIEF, highlighted in red and PaaZ E256Q + TrIEF + NADPH, highlighted in orange). Since NADPH is also a cofactor for PaaABCE, it was necessary to test the NADPH dependency of TrIE in an assay where no PaaABCE was present, i.e. in an assay starting downstream of PaaABCE with PaaG-produced oxepin-CoA as substrate.

**Figure S11 Incubation of tropone with TrIE.** Commercially available tropone was incubated with TrIE and NADPH under shaking. (A) RP-HPLC analysis at 300 nm showing the identical retention time of the pure tropone standard (black) and the same peak from the assay (highlighted in red), which was not converted into any observable product within the time frame of the assay (15 min). (B) UV-visible spectrum of tropone with an absorption maximum around 312 nm.

**Figure S12 Comparison of tropone and tropolone standards to peaks from assay containing TrIE and TrIF.** Verification of the formation of tropolone (4) as main product and tropone as side product by the TrIE-mediated conversion of compound 7 into compound 4. Samples were measured with the HPLC program for the semiprep nucleodur column (see above in method section, 1.18 HPLC analysis).

**Figure S13 Incorporation of  $^{18}\text{O}$  labeled oxygen into tropolone (4) by TrIE.** Distribution of masses ( $m/z$  (-)) for non-labeled oxygen that gets incorporated in tropolone by TrIE (A). The small peak at 123.044 is most likely background noise, as it does not fit the calculated mass of  $^{18}\text{O}$  labeled tropolone of 123.0337. Distribution of masses for assay with  $^{18}\text{O}$ -labeled oxygen (B). The ratio of 4 containing unlabeled or labeled oxygen is roughly 2:1.

**Figure S14 Multiple sequence alignment of Tr1E with known FAD-dependent group A monooxygenases.** The GD-fingerprint, a sequence motif for FAD-binding conserved in this class of enzymes, is highlighted in yellow. Likely catalytic active residues of Tr1E are highlighted in red. The alignment was generated with ClustalOmega, default parameter setting were used.

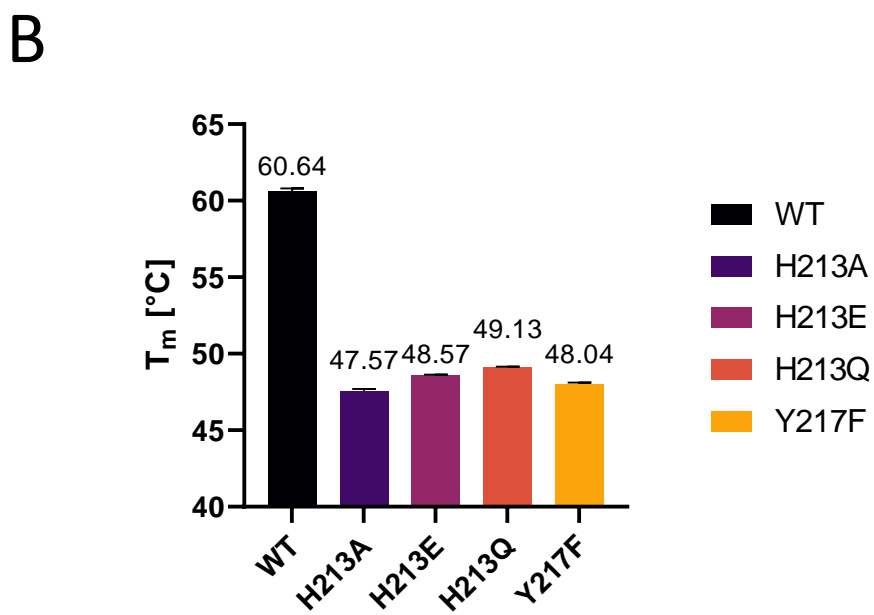

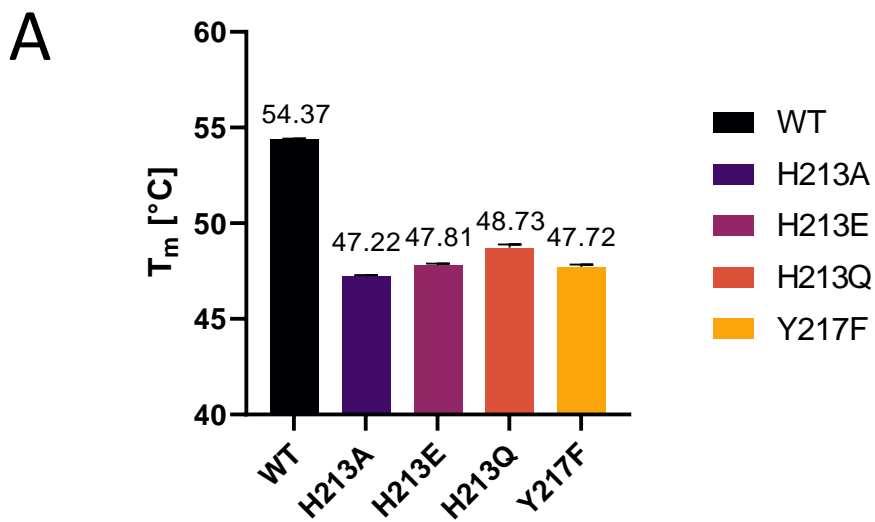

**Figure S15 Phylogenetic distance tree of TrIE and other group A flavoprotein monooxygenases.** The tree with indicated bootstrap values (1,000 replicates) was conducted with the Mega 11 software<sup>6</sup> using Jones-Taylor-Thornton (JTT) matrix based model and maximum likelihood method. Amino acid sequences were aligned using the ClustalW algorithm. Shown are members from the FAD-dependent group A monooxygenases with solved crystal structure (for PDB codes and accession numbers see table S2).

**Figure S19 Representative poses of 7 in the active site of TrIE.** Ten representative structures of **7** in the active site of TrIE after molecular dynamics simulation, clustering of the MD trajectory and energy minimization of the cluster representatives are shown. **7** is shown in teal and the corresponding TrIE and FAD after molecular dynamics simulation and minimization are shown in white. The simulated structures are aligned to the crystal structure of TrIE (shown in blue).

**Figure S20 Comparison of the docked pose of 7 in the active site of TrIE with crystal structures of homologs in complex with their native substrates.** (A) Pose obtained after docking, molecular dynamics simulation, clustering and minimization of representative of largest cluster of 7 in the active site of TrIE (representative structure). (B) Crystal structure of salicylate hydroxylase (SalH) with bound salicylate; PDB ID: 5EVY. (C) Crystal structure of 3-hydroxybenzoate 6-hydroxylase with bound 3-hydroxybenzoate; PDB ID: 4BK1. (D) Crystal structure of TropB with bound 2,4-dihydroxy-3,6-dimethylbenzaldehyde; PDB ID: 6NET. Hydrogen bonds are displayed as black dashes (donor-acceptor distance below 3.5 Å). FAD is shown in yellow, waters are shown as red spheres and the respective substrates are shown in teal.

### Tropolone UV pH 8 (50 mM Tris-HCl buffer)

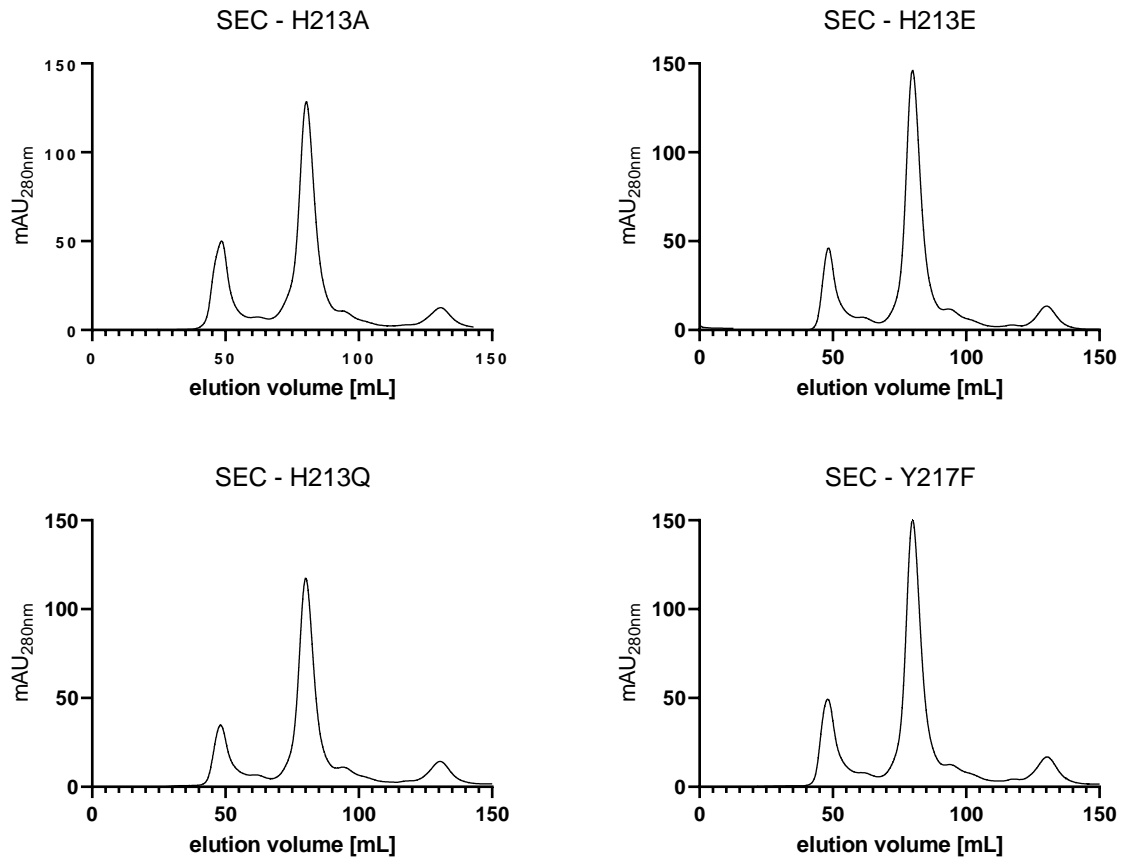

Figure S21 UV-visible spectra of tropolone (4) without (solid line) and with dithionite (dashed line) in 50 mM Tris-HCl pH 8 buffer.

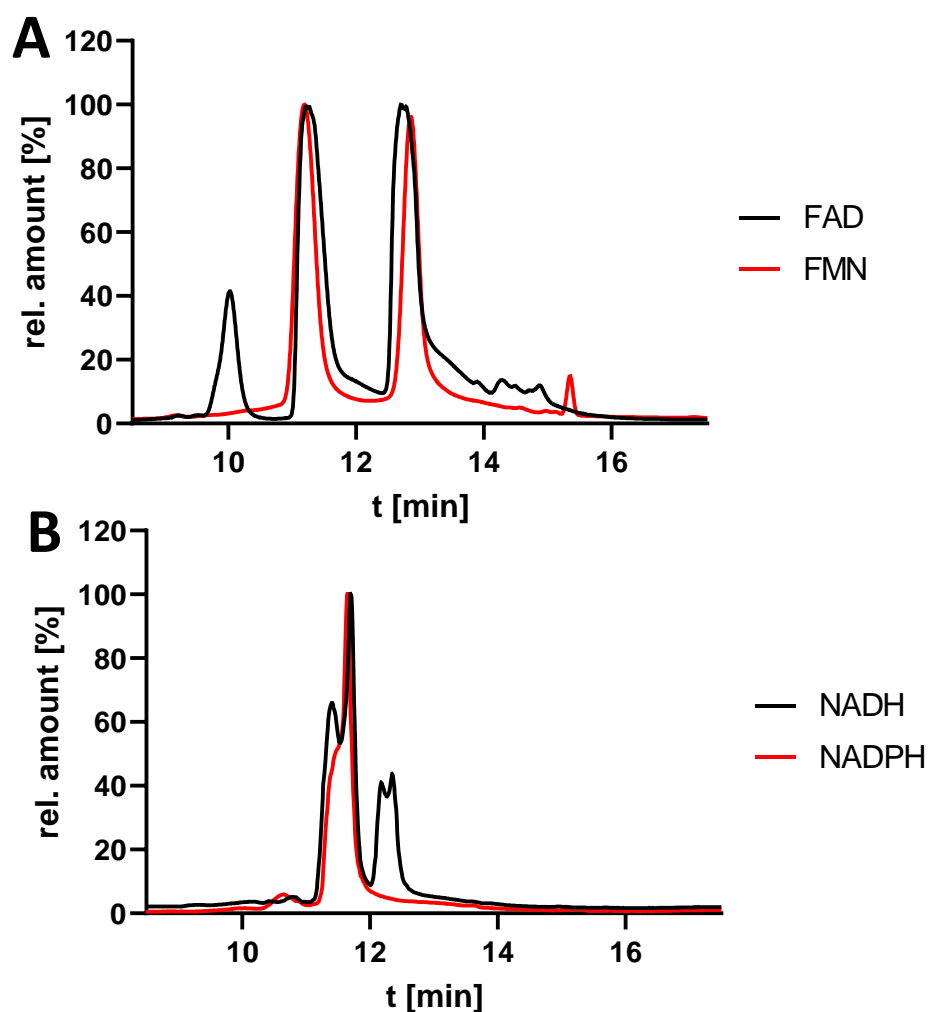

**Figure S22 TrIE mediated re-oxidation of tropolone.** Changes in absorption of 25  $\mu\text{M}$  tropolone upon addition of 200  $\mu\text{M}$  sodium dithionite were measured at 340 nm. The time it took to reach baseline level of absorption was measured as a control. Varying amounts of TrIE were added (0.5, 1 and 2  $\mu\text{M}$ ) and measured ( $N = 4$ ). As additional controls, the experiment was repeated with the addition of FAD (2  $\mu\text{M}$ ) or heat-denatured TrIE (0.5, 1 and 2  $\mu\text{M}$ ) to the tropolone solution.

**Figure S23 SEC of TrIE variants.** Analytical gel-filtration of 6xHis-GB1-tagged TrIE Variants. All variants show a major peak at around 80 mL elution volume indicating the presence of the proteins as monomers (~52 kDa). The peaks at 50 mL elution volume correspond to aggregates and the ones at 130 mL to co-purified impurities from affinity chromatography.

**Figure S24 RP-HPLC analysis (300nm) of the conversion of 7 (highlighted in blue) into 4 (green) by TrIE WT and different variants.** In order to investigate the role of different amino acids in the active site of TrIE, assays with the wild type enzyme and variants were conducted as described in 1.23. Exceptions during handling were using 2.5  $\mu$ M of each enzyme and setting the incubation to 10 minutes. Samples were subsequently quenched with ethyl acetate + 1 % formic acid, before being dried under  $N_2$  gas flow and resuspended in acetonitrile and water. Small amounts of formed product **4** could be observed for the variants H213Q and Y217F. Tropone could be observed as a side-product in all variants and the wild type except for variant H213A. Full substrate (**7**) conversion in the observed timeframe was only noted for the wild type TrIE. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

**Figure S25 Cofactor preferences of TrlD.** (A) Comparison of FAD and FMN usage of TrlCD in an assay with NADH regeneration system. The samples were prepared as described in 1.25, one time with FAD and one time with FMN. Incubation time was set to 2 h and extraction was carried out as described. The samples were analyzed on the semi-preparative HPLC using the XBridge column (see HPLC analysis, 1.17) Only when FAD was used in the assay, a peak corresponding to compound **6** could be observed. (B) Comparison of NADH and NADPH usage of TrlCD in an assay using FAD as Flavin cofactor. The samples were prepared as described in 1.25 with the exception of not using components for the NADH/NADPH regeneration system (sodium formate, formate dehydrogenase and catalase). Incubation time was set to 10 min and extraction was carried out as described. The samples were analyzed on the shimadzu LC-MS system using water and acetonitrile as mobile phase (see 1.19). Only in the sample with NADH a peak corresponding to compound **5** could be observed.

**Figure S26 RP-HPLC analysis (300 nm) of 7-hydroxytropolone (5) and 3,7-dihydroxytropolone (6) formation catalyzed by TrICD over time.** Samples were drawn at 0, 0.5, 1, 2, 3 and 4 hours. An NADH cofactor regeneration system consisting of formate dehydrogenase, sodium formate and catalase was used. Without cofactor regeneration system, only traces of 6 could be observed, even with prolonged incubation. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis, which causes different retention times compared to the method for the semiprep nucleodur column).

**Figure S27 Complete 3,7-dihydroxytropolone (6) biosynthesis pathway reconstituted.** UV traces (280 nm for PaaABCE – TrlF and 300 nm TrlFE – TrlFECD + regeneration system 4h) of RP-HPLC analysis of all involved enzymes in 6 biosynthesis. Samples in lines PaaABCE, PaaG and PaaZ-E256Q were obtained by stopping assays with MeOH, vortexing, centrifuging and drying them in a speedvac. HPLC analysis was done with program 1 (method with buffer containing ammonium acetate, see method section above). All other samples were obtained by extracting assays with ethylacetate + 0.1 % formic acid, vortexing, centrifuging and drying them under N<sub>2</sub> flow. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

**Table S5 HRMS-measurements and calculated masses for compounds 4, 5 and 6**

<b>Compound</b>	<b>Sum formula</b>	<b>Calculated mass [M-H<sup>+</sup>]</b>	<b>Measured mass [M-H<sup>+</sup>]</b>
<b>4</b>	C <sub>7</sub> H <sub>6</sub> O <sub>2</sub>	121.029	121.028
<b>5</b>	C <sub>7</sub> H <sub>6</sub> O <sub>3</sub>	137.024	137.023
<b>6</b>	C <sub>7</sub> H <sub>6</sub> O <sub>4</sub>	153.019	153.019

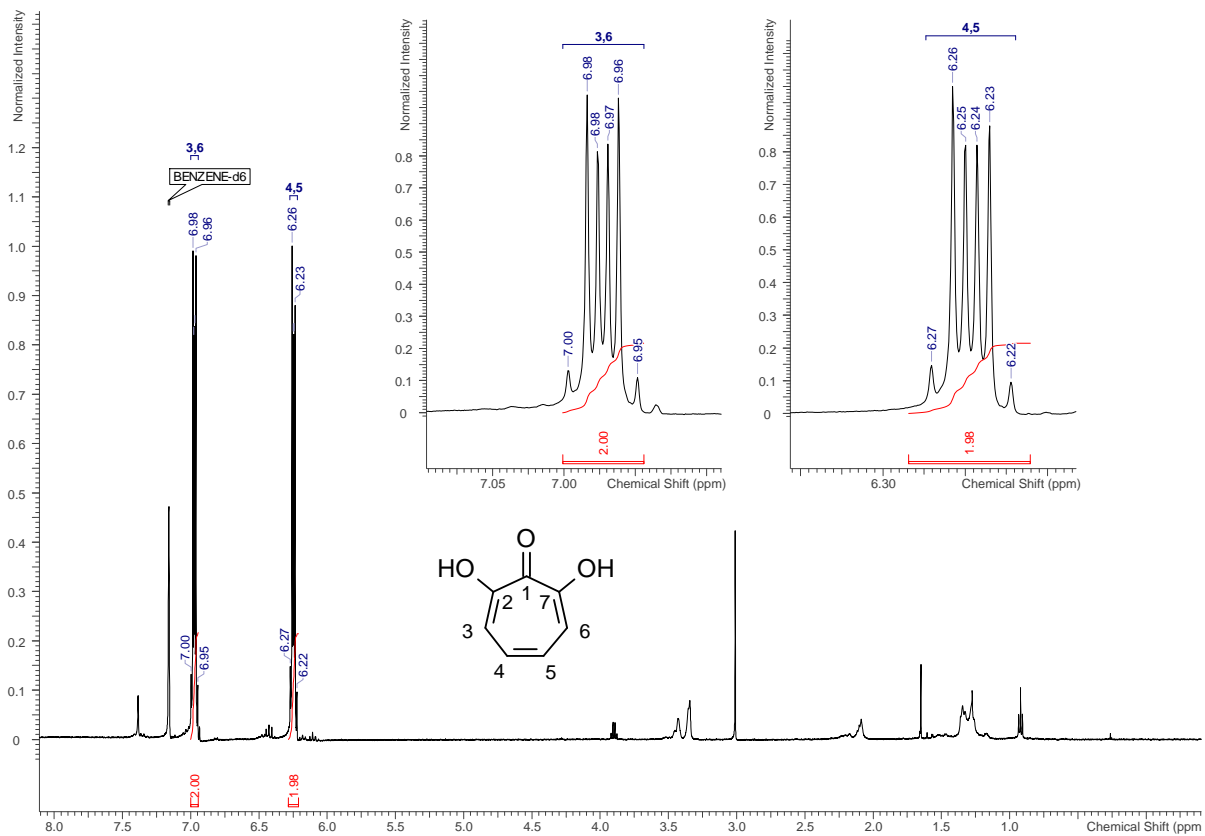

Figure S28 <sup>1</sup>H NMR spectrum of 5 (500 MHz, C<sub>6</sub>D<sub>6</sub>).

Figure S29  $^{13}\text{C}$  NMR spectrum of 5 (126 MHz,  $\text{C}_6\text{D}_6$ ).

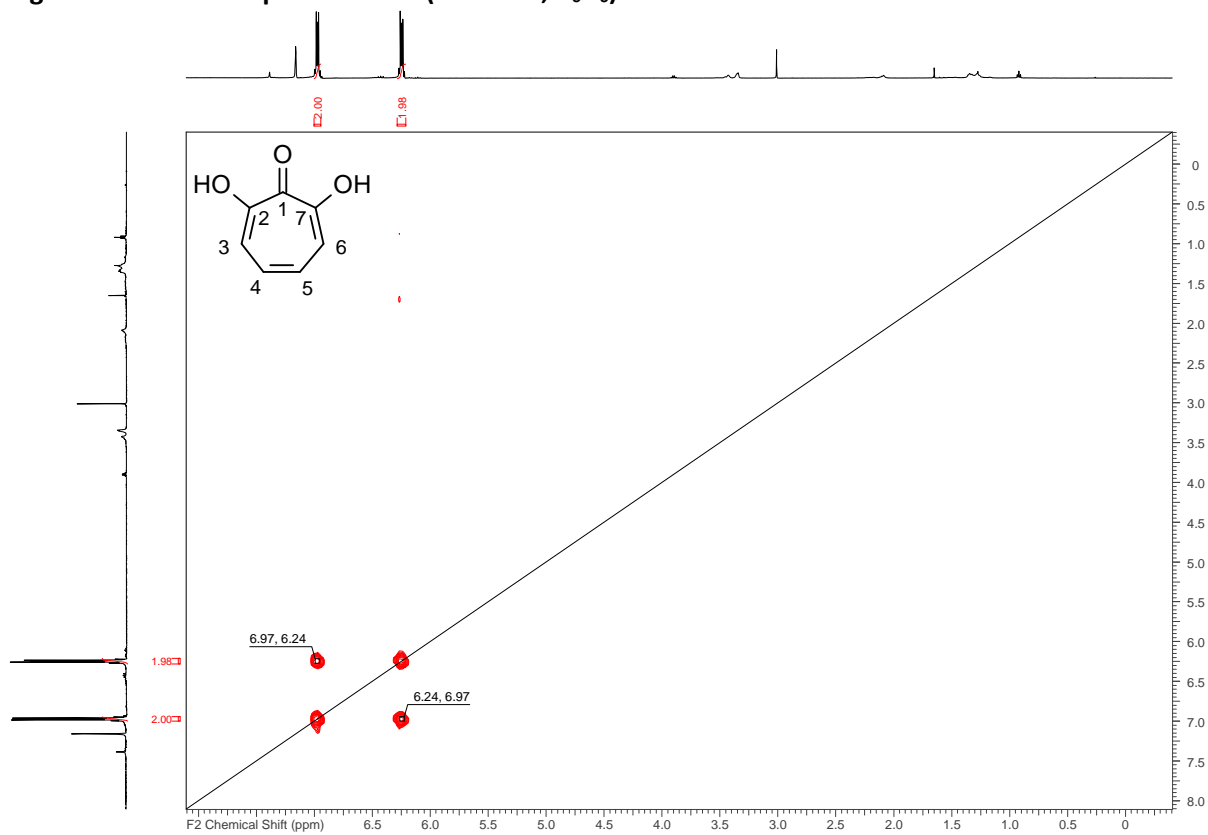

Figure S30 COSY NMR spectrum of 5 (500 MHz,  $\text{C}_6\text{D}_6$ ).

Figure S31 HSQC NMR spectrum of 5 (500 MHz, C<sub>6</sub>D<sub>6</sub>).

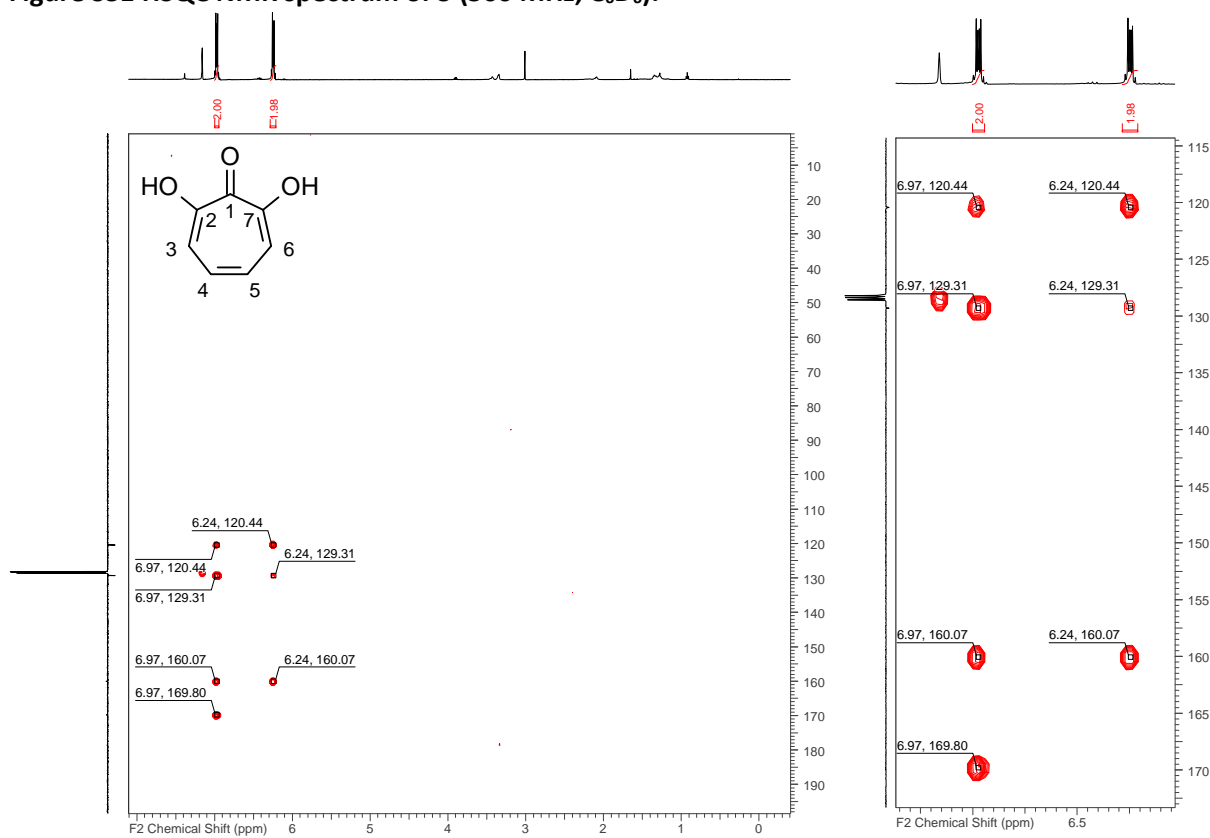

Figure S32 HMBC NMR spectrum of 5 (500 MHz, C<sub>6</sub>D<sub>6</sub>).

**Figure S33 Comparison of the conversion of 4 into 5 and 6 by TrICD and TrIC + Fre including cofactor regeneration system.** RP-HPLC analysis of the conversion of 4 in different assays. Shown are two time points of an assay containing TrIC and its native reductase partner TrID (1 h and 2 h) and two time points from the same assay with TrID substituted by Fre from *E. coli* (after 1 h and 2 h respectively). Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

**Figure S34 Comparison of conversion of tropolone (4) by TrICD with and without cofactor regeneration system.** In both assays, TrICD +FAD were incubated for 2h at 30°C with 4, which was converted into 5 and 6 (see method section). One assay additionally contained the sodium formate NADH regeneration system, while the other one was only supplemented with NADH. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).

**Figure S35 EIC of compounds 4, 5 and 6 obtained during enzymatic assays with TrICD.** Masses were measured on a low resolution LC-MS system in positive mode and theoretical masses for the different compounds were extracted. Samples were measured with the HPLC program for the analytical SunFire column (see above in method section, 1.19 LC-MS analysis).
