1. Experimental section

1.1 Materials characterization

The structures, morphologies and element composition were studied by Scanning electron microscopic (SEM, Hitachi SU8010, Japan) equipped with an EDX spectrometer and transmission electron microscopy (TEM, FEI Tecnai G2 F30, USA). X-ray diffraction (XRD) patterns were conducted on a Bruker D8 (Germany) apparatus with Cu-K α radiation. Raman spectra were collected under a laser excitation of 514 nm by a Raman microscope (Renishaw, England). N₂ adsorption/desorption isotherms were obtained on a micromeritics ASAP 2020 equipment (USA), and the specific surface area and pore size distribution were calculated. X-ray photoelectron spectroscopy (XPS) was performed using a PHI-5100 Versa Probe instrument. Fe 2p, C 1s and N 1s spectra were recorded and calibrated using the C 1s peak (284.8 eV). The determination of absolute content of Fe in catalysts by inductively coupled plasma optical emission spectrometry (ICP-OES, Varian 725-ES). The X-ray absorption data at the Fe K-edge of the samples were recorded at room temperature in transmission mode using ion chambers (referenced samples) and fluorescence excitation mode using a Lytle detector (controlled samples) at beamline BL14W1 of the Shanghai Synchrotron Radiation Facility (SSRF). The station was operated with a Si (111) double crystal monochromator. During the measurement, the synchrotron was operated at 3.5 GeV and the current was between 150-210 mA. The data for each sample were calibrated with standard Fe metal foil. Data processing was performed using the program ATHENA. Extended X-ray absorption fine structure (EXAFS) spectra were fitted using the FEFF 6.0 code.

2. Electrochemical measurements

All electrochemical performance tests are performed at room temperature using a standard three-electrode test system (CHI 760E, Shanghai). The working electrode is a glassy carbon (GC) electrode rotating disk electrode (RDE, 3 mm in diameter). Saturated Ag/AgCl and Pt wires are reference and counter electrodes, respectively. According to the Nernst equation, all potentials in this paper are converted into standard

reversible hydrogen electrode (RHE):

$$E_{(\text{RHE})} = E_{(\text{Ag}/\text{AgCl})} + 0.0592 \text{ pH} + 0.197 \quad (1)$$

Catalyst ink preparation: In this work, 3 mg of the catalyst was dispersed in a mixed solution of 475 μL anhydrous ethanol and 25 μL Nafion and sonicated for 30 min to obtain a well-dispersed catalyst ink.

2.1 ORR performance measurements

Working electrode preparation: The glassy carbon (GC) electrodes were polished for further utilization. Then 3.6 μL of ink was transferred to the polished GC electrode and air-dried at room temperature. The loading of prepared catalysts was $0.3 \text{ mg}\cdot\text{cm}^{-2}$. Commercial Pt/C serve as the reference catalyst with loading of $0.2 \text{ mg}\cdot\text{cm}^{-2}$.

The electrolyte (0.1M KOH) was purified with pure N_2 or O_2 for at least 30min to obtain N_2 or O_2 saturated electrolyte, and then the ORR test was performed. In ORR experiments, cyclic voltammetry (CV) curves were obtained at a scan rate of 10 mV/s. By adjusting the rotation speed (400rpm-2500rpm), the linear sweep voltammetry (LSV) curves were recorded at a scan rate of 10 mV/s. To obtain electrochemical surface area (ECSA) of catalysts, the double-layer capacitance (C_{dl}) is calculated from the CV plots in the region from 1.1 to 1.2 V (vs. RHE) with the scan rates of 3, 5, 10, 15, 20 and 25 mV s^{-1} . The C_{dl} values can be fitted by plotting the $(J_{anodic} - J_{cathodic})/2$ at 1.15 V (vs. RHE) against various scan rates. The linear slope is the C_{dl} . The i-t curves of the catalysts at 0.85 V were collected to evaluate the stable durability of the catalysts. The methanol tolerance of the catalysts was evaluated by adding a certain amount of methanol solution to the O_2 -saturated electrolyte by chronoamperometry.

The electron transfer number (n) is obtained from the LSV curve, using the Koutecky-Levich (K-L) equation:

$$\frac{1}{J} = \frac{1}{J_K} + \frac{1}{J_L} = \frac{1}{J_K} + \frac{1}{B\omega^{1/2}} \quad (2)$$

$$B = 0.62nFC_0D_0^{2/3}v^{-1/6} \quad (3)$$

Where J (mA cm^{-2}), J_L and J_K are the tested, diffusion-limiting and kinetic current densities, respectively. ω (rad s^{-1}) is the angular velocity of the RDE electrode, F

represents the Faraday constant (96,485 C mol⁻¹), D_0 and C_0 are the O₂ diffusion coefficient (1.9×10⁻⁵ cm² s⁻¹) and O₂ concentration (1.2×10⁻⁶ mol cm⁻³) in 0.1 M KOH, respectively, ν is the kinematic viscosity of the electrolyte (0.01 cm² s⁻¹).

2.2 OER and HER performance measurements

Working electrode preparation: The nickel foam is cut to size 1 cm × 1 cm and sonicated in acetone, ethanol and water solutions, respectively. Then a certain amount of catalyst ink was loaded onto a nickel foam and air dried naturally. All catalysts were loaded at 1 mg cm⁻². Pt/C and RuO₂ were loaded at the same 1 mg cm⁻² as the baseline catalysts.

The electrocatalytic activity was examined by measuring the LSV curves in 1 M KOH solution with a scan rate of 10 mV s⁻¹. The electrochemical impedance spectroscopy (EIS) measurement was recorded in the frequency range of 0.01–100,000 Hz with an amplitude of 5 mV. The CP curve was collected at potential at 10 mA cm⁻² to evaluate the durability of catalysts.

2.3 Zn-air batteries assembly

Polished zinc plates (thickness 0.3 mm) and air electrodes (including catalytic active layer and gas diffusion layer) were used as anode and cathode, respectively. The catalytically active layer was mixed with catalyst powder (3 mg), Nafion (20 μL) and ethanol solution (480 mL) by sonication for 60 min, then dropped into nickel foam (1 cm × 1 cm) and dried at room temperature. The catalytically active layer was then laminated to the nickel foam. For comparison, a hybrid catalyst of commercial Pt/C (1 mg) and RuO₂ (1 mg), labeled as Pt/C+RuO₂, was also prepared. The electrolyte was 6 M KOH. All catalysts were loaded at 2 mg cm⁻².

2.4 Overall water splitting device

A two-electrode water splitting device was assembled using Fe₃C-Fe/NC-800 as a bifunctional electrocatalyst for both OER and HER. The Fe₃C-Fe/NC-800 electrocatalyst was fully and uniformly coated on the nickel foam (1 cm × 1 cm) to furnish the electrode with the electrocatalyst loading of 1 mg cm⁻².

The electrocatalytic activity was examined by measuring the LSV curve in 1 M KOH

solution with a scan rate of 10 mV s⁻¹. The CP curve was collected at potential at 10 mA cm⁻² to evaluate the durability of catalysts.

2.5 Density functional theory details

All DFT calculations were carried out by the Vienna ab initio Simulation Package (VASP)^{1, 2}. The Perdew-Burke-Ernzerhof (PBE)³ exchange-correlation functional and projector augmented wave (PAW)⁴ pseudopotential were adopted with spin-polarization. During the structure optimization, the convergence criterion of total energy was set to 10⁻⁶ eV, and the atoms were relaxed until the force acting on each atom was less than 0.01 eV/Å. Gaussian smearing of 0.05 eV to the orbital occupation is applied. A plane-wave cut-off energy of 450 eV was used in all computations. The Brillouin-zone integrations were conducted using Monkhorst-Pack (MP) grids of special points with the separation of 0.06 Å⁻¹. Each slab model was separated from its neighbors by 15 Å vacuum layer spacing. DFT-D3 method of Grimme with zero-damping function were used in van der Waals (vdW) corrections. The free energy profiles, which are efficient in estimating the performance of electrocatalytic reactions, were acquired by applying the computational electrode model (CHE)⁵.

The Gibbs free energies of the ORR were calculated by correcting the DFT energy with zero-point energy and entropy via:

$$\Delta G = \Delta E + \Delta ZPE - T\Delta S \quad (4)$$

where E is the DFT total energy, ZPE is the zero-point energy, T is the environmental temperature, and S is the entropy. For zero-point energy correction and entropy calculations, the vibrational frequencies were calculated by employing density functional perturbation theory.

The theoretical model of Fe₃C-Fe/NC-800, consisting of monatomic FeN₄ and Fe₃C (031) facets, was constructed based on the results of XRD, HRTEM, XPS, and EXAFS characterisation, and ORR, OER, and HER DFT calculations were performed. The experimental results are combined with the DFT calculations for the investigation of the reaction mechanism.

The process of ORR reaction of Fe₃C-Fe/NC-800 in alkaline media can be divided into the following 4 elementary steps:

where * indicates the active site or state.

Supplementary Figures

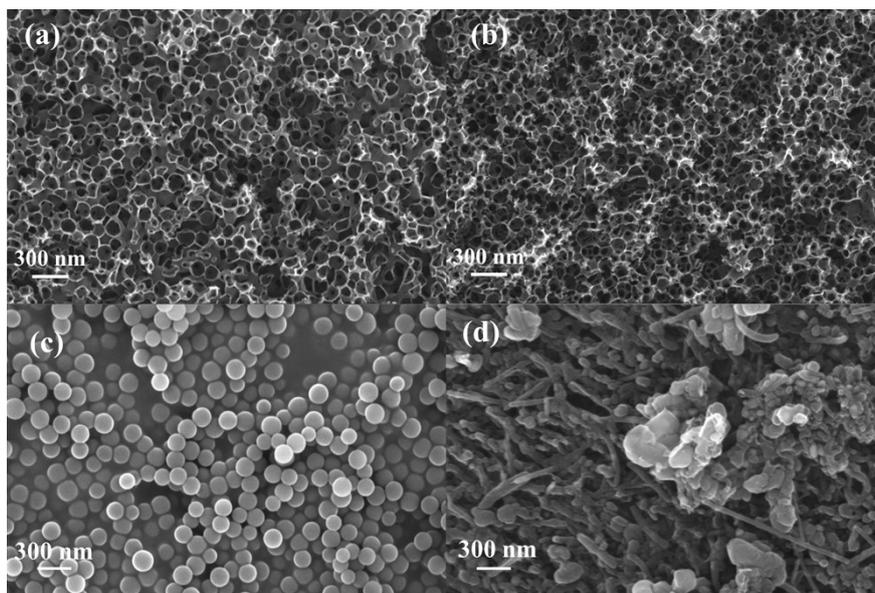

Figure S1 SEM images of (a) $\text{Fe}_3\text{C-Fe/NC-700}$, (b) $\text{Fe}_3\text{C-Fe/NC-900}$, (c) SiO_2 and (d) HM-800.

According to the SEM images, the catalysts $\text{Fe}_3\text{C-Fe/NC-700}$ and $\text{Fe}_3\text{C-Fe/NC-900}$ also had interconnected honeycomb structures, and when the calcination temperature was 900 °C, it was observed that part of the honeycomb structure on the surface of the catalyst $\text{Fe}_3\text{C-Fe/NC-900}$ was disrupted, which suggests that the appropriate calcination temperature helps to retain honeycomb structures.

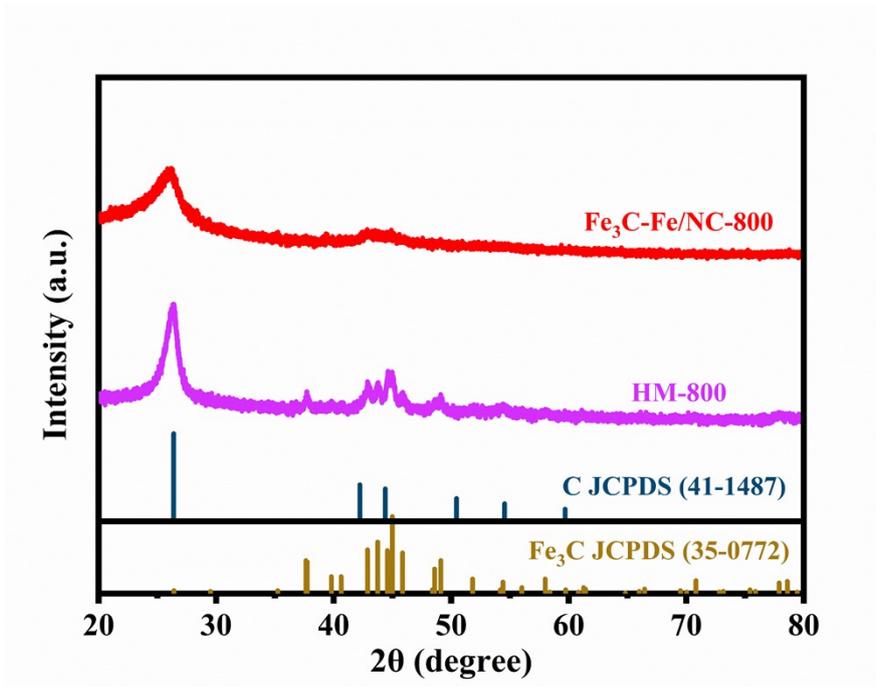

Figure S2 XRD of Fe₃C-Fe/NC-800 and HM-800.

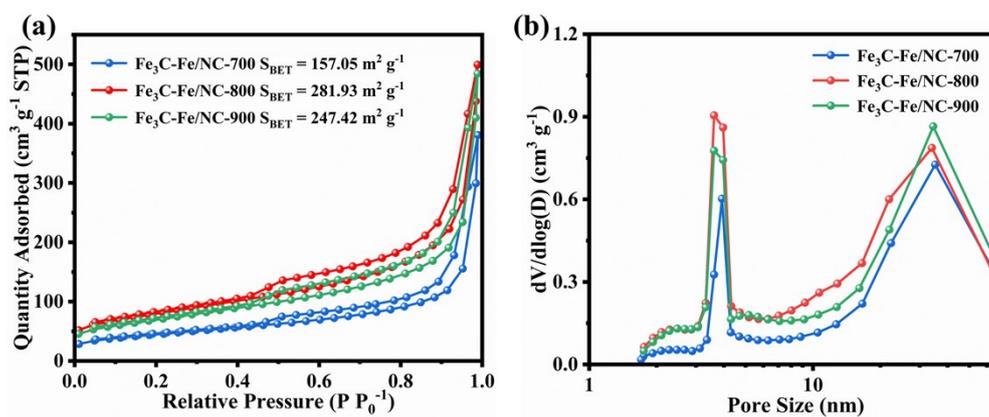

Figure S3 (a) N_2 adsorption and desorption isotherms and (b) pore size distribution of $Fe_3C-Fe/NC-700$, $Fe_3C-Fe/NC-800$ and $Fe_3C-Fe/NC-900$.

According to the N_2 adsorption desorption curves, the catalysts at different calcination temperatures have typical type IV isotherm type. This indicates the presence of a large number of mesoporous structures in the prepared catalysts. The pore size distribution shows small and large mesopores centred around at 3.6 nm and 34 nm. And it can be seen that $Fe_3C-Fe/NC-900$ has more large mesoporous structures from Figure S1b, which is consistent with the SEM results. The specific surface area of $Fe_3C-Fe/NC-800$ was $281.93 m^2 g^{-1}$, which was larger than that of $Fe_3C-Fe/NC-700$ ($157.05 m^2 g^{-1}$) and $Fe_3C-Fe/NC-900$ ($247.42 m^2 g^{-1}$), suggesting that the carbonisation temperature also has effect on the specific surface area of the material. Therefore, suitable carbonisation temperature is more conducive to the generation of a larger specific surface area, allowing more active sites to be exposed^{6,7}.

Overall amount	100.00		100.00

Table S9 Total number of spectra of distribution maps after HER stability test.

Elemental	wt%	wt% Sigma	At%
C	52.15	0.33	77.12
N	1.45	0.23	1.84
O	7.92	0.09	8.80
Fe	38.43	0.36	12.24
Overall amount	100.00		100.00

Table S10 Comparison of the performance of Fe₃C-Fe/NC-800 with other reported catalysts for Zn-air batteries.

Catalyst	Open circuit voltage /V	Specific capacity /mA h g ⁻¹	Ref.
Fe ₃ C-Fe/NC-800	1.46	813	This work
Fe-N _x /Fe ₃ C@NC	1.40	705	27
Co ₂ P/CoNPC	1.425	-	28
Co ₄ N@NC-2	1.48	769.4	29
Co ₄ NC@NC	1.38	759.6	30
Co-N-S-C	1.44	-	13
FeCo/Co ₂ P@NPCF	1.44	-	21
NCNT/Ni-NiMn ₂ O ₄	1.2	502	24
3D Fe-S, N-C	1.44	817	31
Fe-S, N-C-950	1.459	660	32
Fe ₃ C-FeN/NC-2	1.41	745	33
FeCo-N-C-700	1.39	518	34

Table S11 Comparison of the performance of Fe₃C-Fe/NC-800 with other reported catalysts for overall water splitting.

Catalyst	Open circuit voltage /V	Current density (mA cm ⁻²)	Ref.
Fe ₃ C-Fe/NC-800	1.70	10	This work
Fe ₃ C-Co/NC	1.77	10	9
Co ₉ S ₈ @MoS ₂	1.67	10	20
FeCo/Co ₂ P@NPCF	1.68	10	21
Co _{0.85} Se@NC	1.76	10	23
CoS _x /NCS	1.83	10	35
3D-CNTA	1.68	10	36
FeNiP/NPCS	1.71	10	37
Fe ₂ P/Co@NPC	1.73	10	38
Co@NCL	1.70	10	39
Ir@NG-750	1.70	10	40

Table S12 ΔG of ORR from DFT calculations.

Reaction	$\Delta G_{\text{Fe3C/Fe-N4}}/\text{eV}$	$\Delta G_{\text{Fe-N4}}/\text{eV}$	$\Delta G_{\text{Fe3C}}/\text{eV}$
$* + \text{O}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) + \text{e}^- \rightarrow *\text{OOH} + \text{OH}^-$	-0.158	-1.020	-0.973
$*\text{OOH} + \text{e}^- \rightarrow *\text{O} + \text{OH}^-$	-0.683	-1.054	-2.973
$*\text{O} + \text{H}_2\text{O}(\text{l}) + \text{e}^- \rightarrow *\text{OH} + \text{OH}^-$	-0.692	-0.186	0.970
$*\text{OH} + \text{e}^- \rightarrow * + \text{OH}^-$	-0.078	0.694	1.366
