## **Text S1. Characterization**

X-ray diffraction (XRD) was conducted on Bruker D8 Advanced instrument (Germany), equipped a Cu K $\alpha$  radiation source ( $\lambda = 1.54 \text{ \AA}$ , 40 kV, 30 mA) at 10 °/min. X-ray photoelectron spectroscopy (XPS) was used on a Thermo Scientific ESCALAB Xi<sup>+</sup> instrument (Al K $\alpha$  X-ray source) to study the chemical states of the materials. Scanning electron microscopy (SEM, TESCAN MIRA LMS) equipped with EDS and Transmission electron microscopy (TEM, FEI Tecnai F20, the Netherlands) were performed. Fourier transform infrared spectroscopy (FT-IR) was carried out on a Nicolet iS50FTIR instrument. N<sub>2</sub> adsorption-desorption isotherm and UV-vis DRS spectra were obtained on a Nova Station A (Quantachrome) and Shimadzu UV-2401 spectrophotometer (Germany), respectively. Photoluminescence (PL) analysis and Time-resolved PL decay curves (TRPL) were conducted on a Varian Cary Eclipse spectrometer. The electron spin resonance (EPR) was conducted on a Bruker EMXplus-6/1 (Germany). The electrochemical impedance spectroscopy (EIS), photocurrent response (TPR), and Mott-Schottky curves were carried out on an electrochemical workstation (CHI760E). The water contact angles were analyzed on an angle measuring instrument (JC 2000D1, Zhongchen Digital Equipment Co. Ltd., China). Solid-state <sup>13</sup>C magic angle spinning (MAS) NMR spectra were recorded on Bruker AVANCE III HD 400 MHz WB solid-state NMR spectrometer at room temperature.

## **Text S2. Photocatalytic Hydrogen Evolution Test**

The photocatalytic hydrogen evolution (PHE) experiments was measured on an online gas monitoring system on Labsolar-6A with a 300 W Xe lamp (BEIJING

Perfectlight Technology Co. Ltd.,  $\lambda \geq 400$  nm). Specifically, photocatalysts (10 mg) was sonicated and dissolved in 100 mL (10 vol%) TEOA solution containing 3 wt%  $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$  as co-catalyst. The system temperature is controlled by circulating condensate at 5 °C. The photocatalytic system was further evacuated for 30 min and then 20 mL of argon was injected as a carrier gas to promote hydrogen circulation. After that, the photocatalytic test was performed. The content of hydrogen was examined by gas chromatography (GC9790II PLF-01). In addition, cyclic experiments were conducted by repeating the above experimental steps. The apparent quantum yield (AQY) was evaluated under the same conditions at monochromatic light. The formula is as follows.

$$\text{AQY} = \frac{\text{Number of reacted electrons}}{\text{Number of incident light photons}} \times 100 \%$$

### **Text S3. Photocatalytic Degradation Test**

Photocatalytic degradation performance of the samples was measured by decomposing TC solution under visible light. Experimentally, 50 mg catalysts were dissolved ultrasonic into 50 mL of TC solution (20 ppm) and continuously stirred for 30 min under dark condition to achieve adsorption-desorption equilibrium. After that, the visible light is turn on and photocatalysis is going on. During the period of 30 min, 3.5 mL of reactive suspension was extracted and was collected by filtration with 0.45  $\mu\text{m}$  filters. The absorption spectra of the supernatant were conducted on a UV-vis spectrophotometer (UV 9600) by measuring absorbance data at 357 nm. And then, changes in pollutant concentrations were measured according to Lambert-Beer law.

### **Text S4. DFT details**

Density functional Theory (DFT) calculations were performed on the CASTEP module to construct N defect models. The generalized-gradient-approximation (GGA) of the Perdew–Burke–Ernzerhof (PBE) functional was utilized to study the exchange relationship calculation. Typically, the kinetic cutoff energy is 517.04 eV and k-point mesh is 2\*2\*1 for structure optimization. During the calculation process, the self-consistent field tolerance, maximum force, maximum displacement, and maximum stress are  $1.0 \times 10^{-6}$  eV,  $0.03 \text{ eV \AA}^{-1}$ ,  $0.001 \text{ \AA}$ , and 0.05 GPa per atom, respectively. The band structure, Gibbs free energy, and potential density of states (PDOS) of pristine and N defected g-C<sub>3</sub>N<sub>4</sub> were calculated after geometry optimization.
