Comparison of the L_S_{3a} and L_S_{3aa} structures. In high-resolution XFEL structures of the OEC, a water molecule is typically observed between W₃ and Glu189 and another between W₃ and W₂. In our LOS model, we simply label these two experimentally observed waters as W_A (between W₃ and Glu189) and W_B (between W₃ and W₂). Whereas in Siegbahn's original HOS model, W_A and W_B were introduced as additional waters migrating toward the OEC, in our model they correspond directly to crystallographically observed water sites in the XFEL structures.

As discussed in the manuscript, our calculations start from the intermediate L_S_{3a} (Fig. 3 and Figs S1 and S2). Our initial exploration of L_S_{3a} considered a conformer consistent with experimentally reported XFEL models, containing a water molecule between W₃ and Glu189 and another between W₃ and W₂. However, this intermediate (denoted L_S_{3aa}, Fig. S3) was found to be less stable than L_S_{3a} at both the B3LYP and B3LYP* levels of theory, in terms of both electronic energy and free energy. Accordingly, the L_S_{3a} structure shown in Fig. S1 and S2 was adopted as the reference point for the mechanistic calculations presented in this study.

The higher stability of L_S_{3a} relative to L_S_{3aa} can be attributed to differences in the hydrogen-bonding environment around W₂. In L_S_{3a}, W₂ is an OH ligand with high electron density localized on the oxygen atom, enabling simultaneous hydrogen-bond interactions with both W₃ and W_B. These simultaneous interactions provide additional stabilization. In contrast, in L_S_{3aa}, W₂ forms a hydrogen bond only with W_B, while the interaction with W₃ is absent, leading to reduced stabilization.

A similar hydrogen-bond-based rationale was employed by us under the subtitle "*Effect of the W3' Water Molecule on Proton Transfer and O–O Coupling*" in the Supporting Information of our recent publication (ref 17).

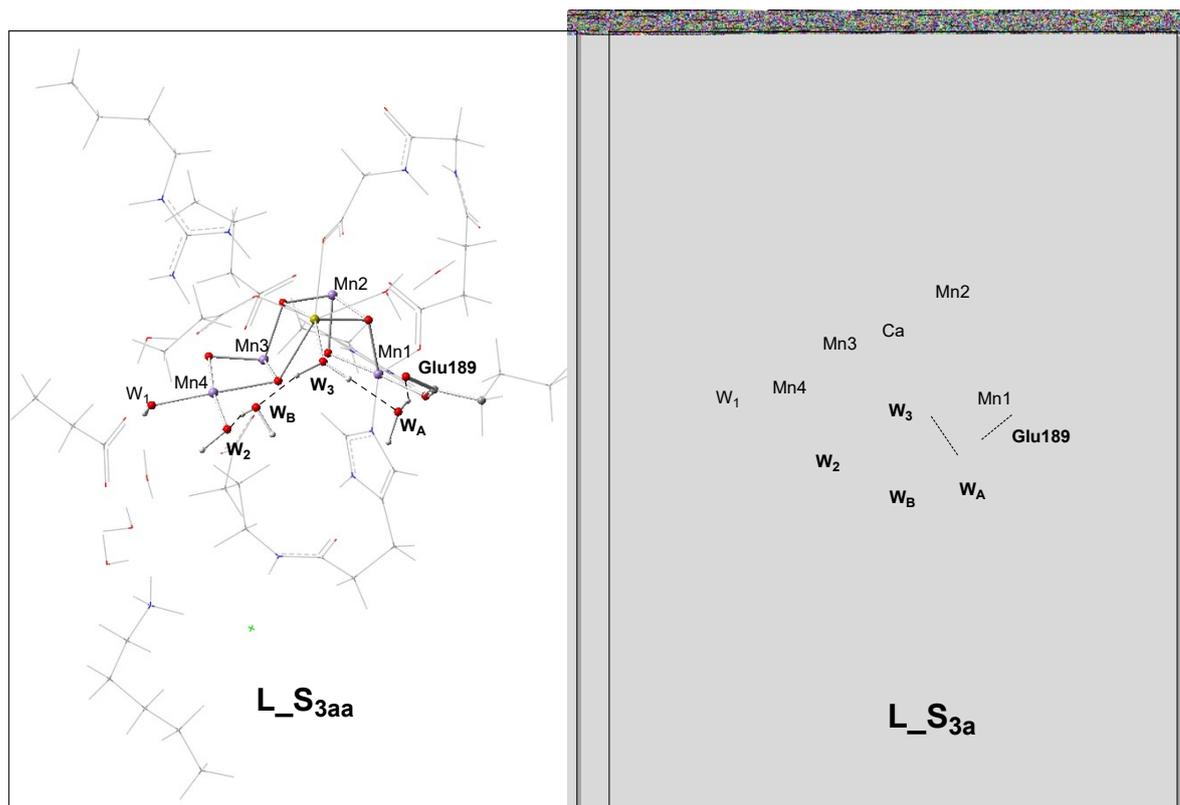

Fig. S3 3D structures for L_{S3a} and L_{S3aa} .

Why oxidation occurs at Mn3 during the $S_2 \rightarrow S_3$ transition. Our assignment of the oxidation sequence in the LOS model follows the literature, in which the order of Mn oxidation states has been discussed in detail. We previously reviewed and summarised these studies in 2021 (see ref2).

Nevertheless, this assignment is further supported by our calculations (Fig. S4). As shown in Fig. 3, in the S_3 state of the LOS model only Mn2 is in the +IV oxidation state, while the remaining Mn centres are +III. Consequently, oxidation during the $S_2 \rightarrow S_3$ transition must occur at Mn1, Mn3, or Mn4. Computational attempts to localise oxidation at Mn1 consistently collapsed to oxidation at Mn3 or Mn4. This behaviour arises because Mn1 is intrinsically five-coordinate in the S_2 state, making its oxidation unfavourable, whereas Mn3 and Mn4 are six-coordinate and therefore more readily oxidised. Although we were able to locate an S_3 state in which Mn4 is oxidised instead of Mn3, at the B3LYP (B3LYP*) level, this state is approximately 16.5 (16.0) kcal/mol higher in free energy than the case in which Mn3 is oxidised (Fig. S4), demonstrating that oxidation at Mn3 during the $S_2 \rightarrow S_3$ transition is energetically preferred, in agreement with previous studies (ref 2).

The lower propensity of Mn4 to undergo oxidation relative to Mn3 is likely associated with its ligand environment, which includes the bridging carboxylate ligands Asp170 and Glu333. These weak σ -donor ligands stabilise the Mn4 d_z^2 orbital along the Asp170–Mn4–Glu333 axis, lowering its energy and reducing its tendency to undergo oxidation.

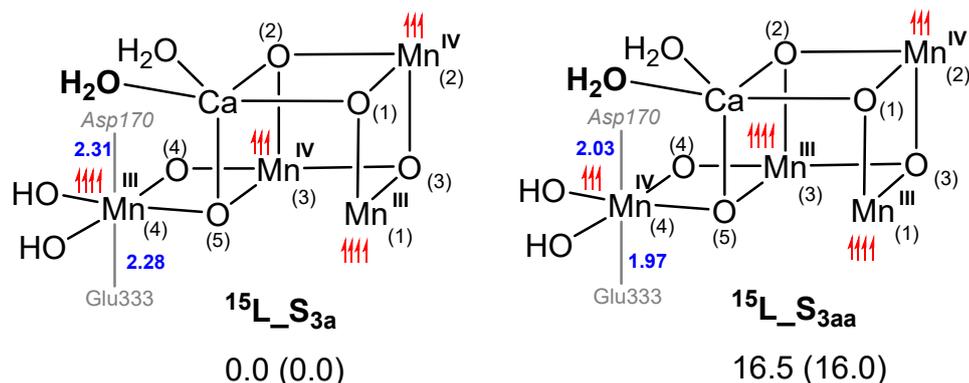

Fig. S4 Calculated structures of L_S_{3a} and L_S_{3aa} and their relative free energies in the LOS model. The relative free energies outside parentheses correspond to the IEFPCM/B3LYP-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level, and those in parentheses to the IEFPCM/B3LYP*-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level.

Justification of the structural model used in this study. We note that the structural model adopted from Siegbahn remains appropriate and consistent with current crystallographic understanding of the OEC. In this model, all first- and second-coordination-sphere ligands are explicitly included and correctly positioned, indicating that the essential structural features of the active site are fully retained. Importantly, the structures employed in this work were not treated as rigid single-point models; rather, they were fully geometry-optimised prior to subsequent single-point energy calculations. As a result, any potential inaccuracies in structural parameters present in the initial coordinates are eliminated during optimisation.

Moreover, this structural model continues to be used by Siegbahn himself in his more recent studies (*J. Phys. Chem. B* 2023, 127, 6643–6647), supporting its ongoing validity. In addition, in our own recent work (ref. 14), we explicitly demonstrated that the Siegbahn model is fully appropriate for describing the OEC. In that study, we investigated the mechanistic details of O–O bond formation and O₂ release within the LOS framework and showed that calculations performed using the Siegbahn model yield results very similar to those obtained using a model constructed from more recent crystallographic data reported by Bhowmick et al. (ref. 16).

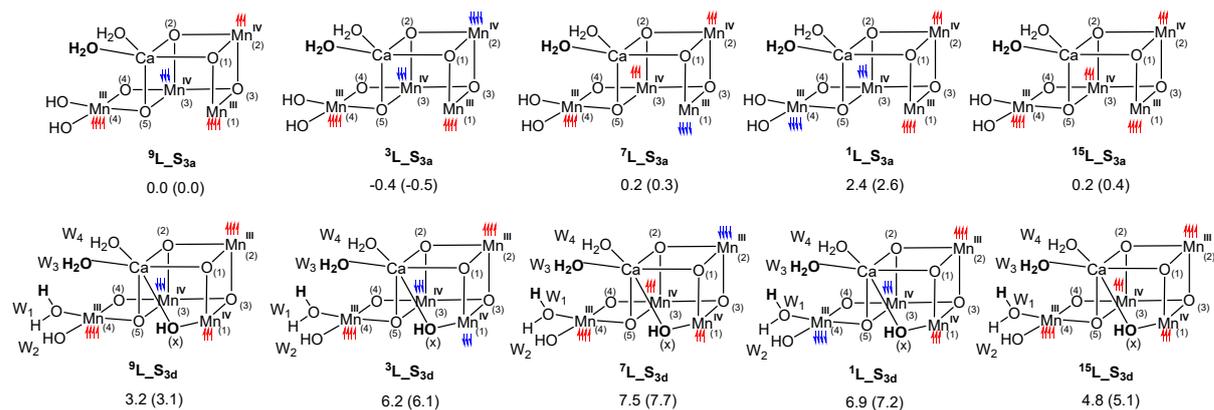

Fig. S5 Optimised free-OEC structures of L_{S3a} and L_{S3d} computed for multiple spin states (antiferromagnetic singlet, triplet, septet, and nonet, and ferromagnetic 15-et), with relative free energies given in kcal/mol, where $15L_{S3a}$ is considered as the reference energy point. The relative free energies outside parentheses refer to calculations performed at the IEFPCM/B3LYP-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level, whereas those in parentheses refer to calculations performed at the IEFPCM/B3LYP-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level.

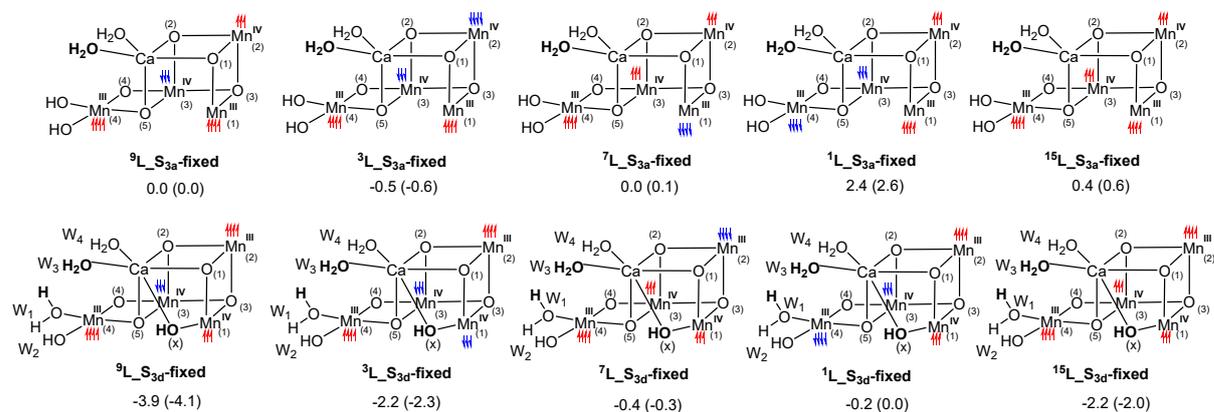

Fig. S6 Optimised fixed-OEC structures of L_{S3a} -fixed and L_{S3d} -fixed computed for multiple spin states (antiferromagnetic singlet, triplet, septet, and nonet, and ferromagnetic 15-et), with relative free energies given in kcal/mol, where $15L_{S3a}$ -fixed is considered as the reference energy point. The relative free energies outside parentheses refer to calculations performed at the IEFPCM/B3LYP-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level, whereas those in parentheses refer to calculations performed at the IEFPCM/B3LYP-D3/6-311+G(2d,p),SDD//IEFPCM/B3LYP-D3/6-31G(d),SDD level.

Contribution of His337 to Mn1 → Mn2 electron transfer in the constrained model.

When electron transfer occurs from Mn1 to Mn2 in **L_S_{3c}-fixed**, the oxidation state of Mn2 is reduced from +IV to +III, stabilising the system by approximately 13.6 kcal/mol and leading to formation of **L_S'_{3d}-fixed** (Fig. S7). This stabilisation arises from the Mn1–ligand restraints, which enforce a Mn(IV)-type coordination geometry at Mn1. Upon reduction of Mn2, a Jahn–Teller distortion is induced at this centre, resulting in increased basicity of O3. This effect is clearly reflected in the shortening of the O3–H(His337) distance from 1.72 Å in **L_S_{3c}-fixed** to 1.60 Å in **L_S'_{3d}-fixed** (Fig. S7). The increased basicity of O3 favours full proton transfer from His337, leading to formation of **L_S_{3d}-fixed**, which is approximately 7 kcal/mol more stable than **L_S'_{3d}-fixed**.

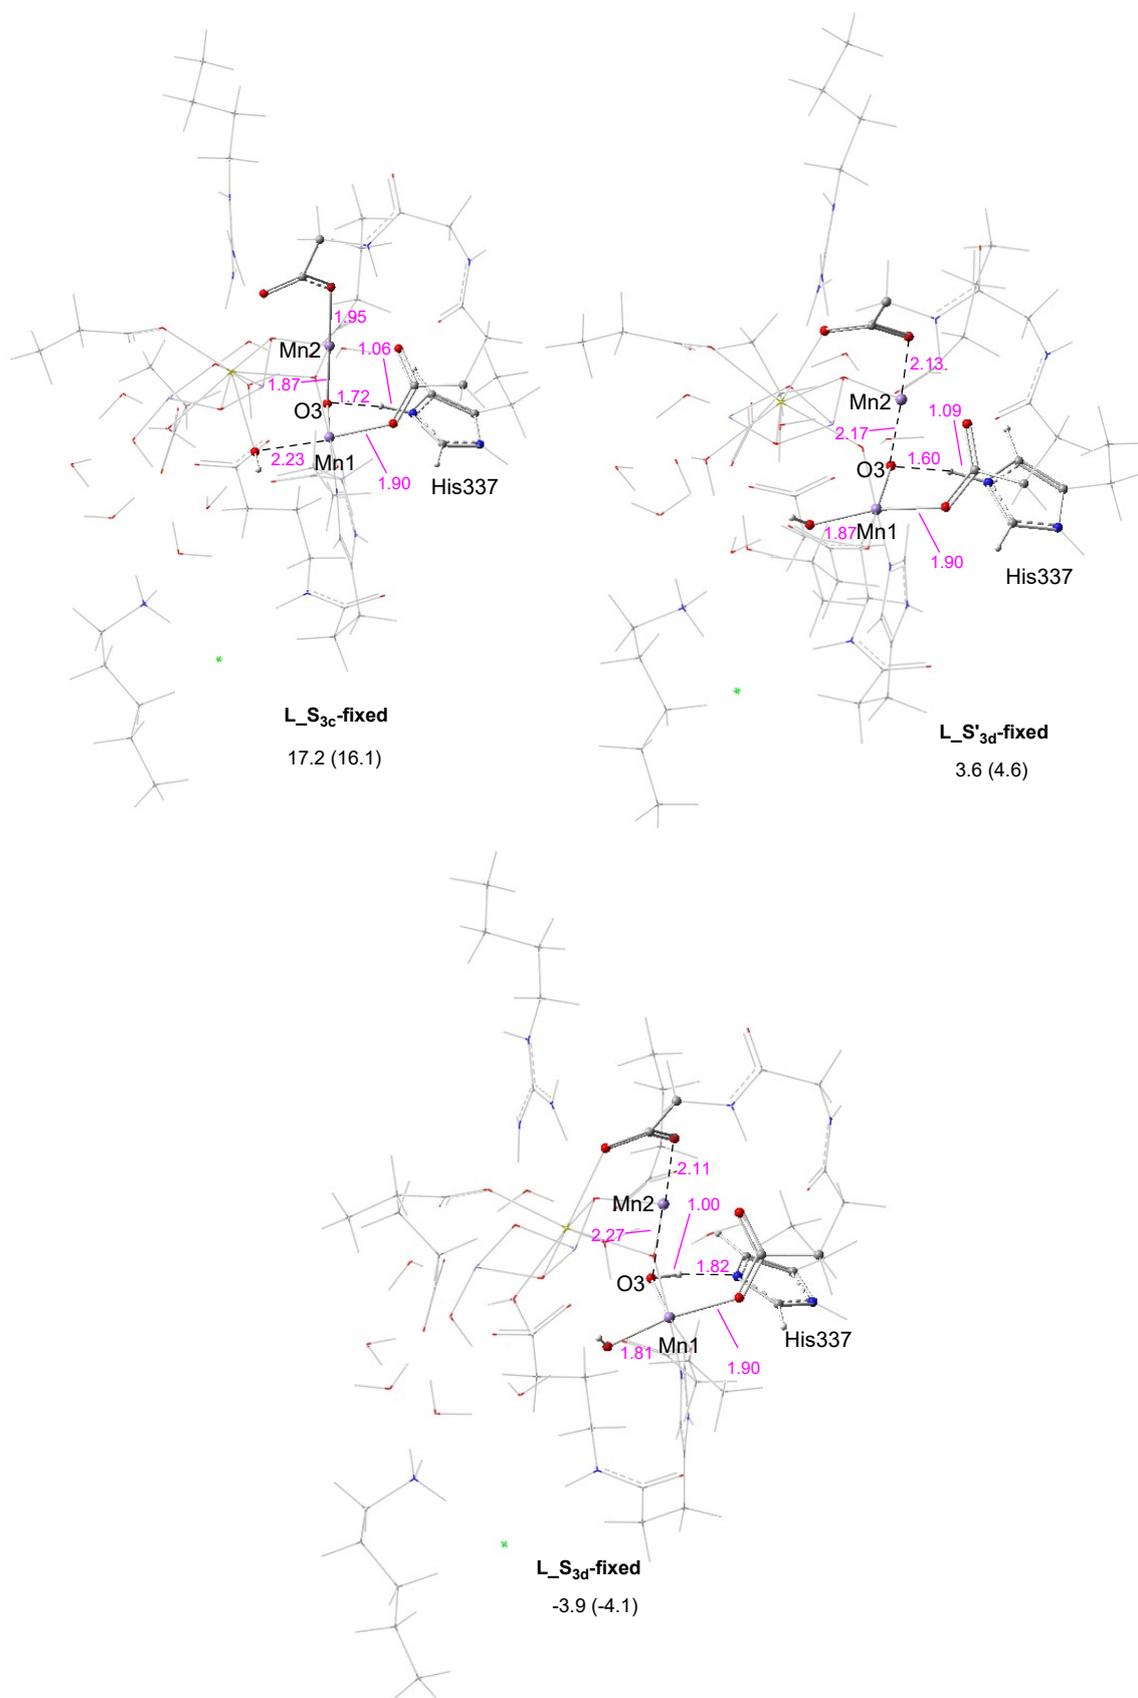

Fig. S7 Structural changes and relative free energies associated with Mn1 \rightarrow Mn2 electron transfer under geometric constraints in the fixed-OEC model. Selected bond distances are given in Å.

Computational Details. Gaussian 16¹ was used to fully optimize all the structures reported in this study at the B3LYP level of theory.² For all calculations, solvent effects were incorporated

using the IEFPCM solvation model³ with a dielectric constant (ϵ) of 6.0. The Grimme empirical dispersion was added with the GD3 term for all the calculations.⁴ For geometry optimizations, the SDD basis set with effective core potential (ECP) was chosen to describe the Ca and Mn ions and the 6-31G(d) basis set was employed for all other atoms.⁵ This basis set combination will be referred to as BS1. Transition structures were located using the Berny algorithm. Frequency calculations were performed at the same level of theory as the structural optimisations to confirm that each transition structure exhibits a single imaginary frequency corresponding to the intended reaction coordinate, and to obtain the enthalpy and entropy corrections required for calculating Gibbs free energies. Intrinsic reaction coordinate (IRC) calculations were used to confirm the connectivity between transition structures and minima.⁶ To enhance the precision of the energies derived from the IEFPCM/B3LYP-D3/SDD, 6-31G(d) calculations, single-point energy calculations were carried out on all structures using both the B3LYP*-D3 and B3LYP-D3 functionals with a larger basis set (BS2), while still applying the IEFPCM solvation model. This larger basis set employs the SDD effective core potential (ECP) for Mn and Ca and the 6-311+G(2d,p) basis set for all other atoms, which includes diffuse functions as recommended for this type of system.⁷

The choice of B3LYP*, a modified hybrid functional with 15% exact Hartree–Fock exchange, is based on its reliable performance in describing spin-state energetics in transition metal (TM) systems⁸ and its good agreement with experimental redox behaviour in the OEC system.⁹

The antiferromagnetic electronic configurations were obtained through the application of the broken symmetry (BS) approach.¹⁰

In the OEC model (Figure 9), all amino acid residues directly bound to Mn and Ca are included, namely His332, Glu189, Asp342, Ala344, Glu354, Asp170, and Glu333. Additionally, the model incorporates His337 and Arg357, and the backbones of Leu343 and Ser169, as well as

a portion of Gly171. Seven water molecules, positioned at crystallographic locations, are also included. The cluster in the LOS model formally has a -1 net charge. We have adopted this structural model from a recent computational study by Siegbahn et al.,¹¹ who interpreted the 1.9 Å crystallographic data of PSII¹² as representative of the S₃ state and used it to build their computational model. In this setup, the α -carbons and peptide chains were fixed, to account for the constraints imposed by the enzyme surroundings on the active site.

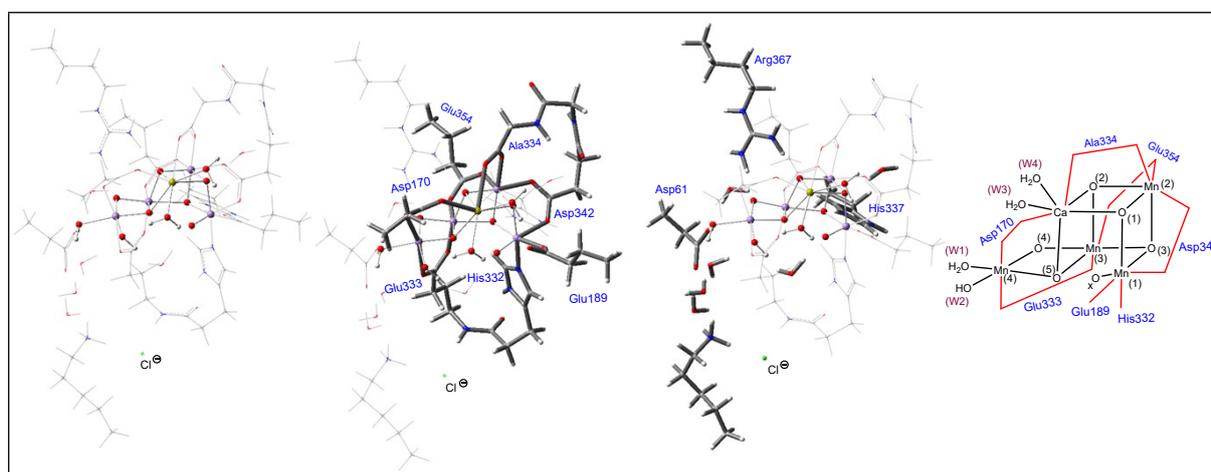

Fig. S8 Model complex used in this study for S₃ state. The first structure from the left represents the active site of PSII. The second structure includes the first coordination sphere ligands along with the active site. The third structure encompasses the second coordination sphere ligands and the active site.

Table S2. Cartesian coordinates for all optimised structures, together with total potential energies, enthalpies, and Gibbs free energies calculated at the IEFPCM/B3LYP-D3/SDD,6-31G(d) level, and single-point energies obtained at the IEFPCM/B3LYP-D3/SDD,6-

311+G(2d,p)//IEFPCM/B3LYP-D3/SDD,6-31G(d) and IEFPCM/B3LYP*-D3/SDD,6-311+G(2d,p)//IEFPCM/B3LYP-D3/SDD,6-31G(d) levels in a solvent with $\epsilon = 6.0$.

In the Cartesian coordinates, a '-1' sign following an atom indicates it was fixed, while a '0' signifies it remained fully unconstrained during the optimization process.
