### The electron transfer within Pt-Zr on the surface of Al<sub>2</sub>O<sub>3</sub>

As shown in Fig. S1(a), due to the relatively slow reaction rate, both Pt/Al<sub>2</sub>O<sub>3</sub> and Pt-Zr/Al<sub>2</sub>O<sub>3</sub> exhibited a continuous induction period during the 56-hour reaction. In contrast, Zr/Al<sub>2</sub>O<sub>3</sub> showed a 30-hour induction period and an 18-hour stability period, after which the  $X_{EB}$  declined while the  $S_{ST}$  stabilized. The  $X_{EB}$  and  $S_{ST}$  of the three catalysts at the 30th hour of the reaction and the  $C_{coke}$  after 56 hours of reaction are presented in Table S1 (Pt-Zr/Al<sub>2</sub>O<sub>3</sub> and Zr/Al<sub>2</sub>O<sub>3</sub>) and Table 1 (Pt/Al<sub>2</sub>O<sub>3</sub>). The TGA curves are depicted in Fig. S4. Among Pt/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Pt-Zr/Al<sub>2</sub>O<sub>3</sub> catalysts, Zr/Al<sub>2</sub>O<sub>3</sub> exhibited the highest  $X_{EB}$  (54.6%) and the lowest  $C_{coke}$  (5.1%); however, it showed the lowest  $S_{ST}$  (86.0%), with benzene as the main by-product. Pt/Al<sub>2</sub>O<sub>3</sub> showed the opposite trend: the lowest  $X_{EB}$  (25.7%), highest  $C_{coke}$  (12.8%), and highest  $S_{ST}$  (97.0%). The Pt-Zr/Al<sub>2</sub>O<sub>3</sub> catalyst exhibited intermediate behavior, with a  $S_{ST}$  of 96.1%, significantly higher than that of Zr/Al<sub>2</sub>O<sub>3</sub> due to Pt-Zr interaction. Its  $X_{EB}$  (33.1%) was higher than that of Pt/Al<sub>2</sub>O<sub>3</sub>. In comparison, its  $C_{coke}$  (11.3%) was lower, demonstrating that Zr addition improves the coke resistance of the Pt-based catalyst and enhances the catalytic activity slightly.

H<sub>2</sub>-TPR and XPS examined the influence of Pt-Zr interaction on the catalyst properties. H<sub>2</sub>-TPR analysis was only applied to Pt/Al<sub>2</sub>O<sub>3</sub> and Pt-Zr/Al<sub>2</sub>O<sub>3</sub>, as ZrO<sub>2</sub> itself is not reducible. Fig. S1(b) reveals a single reduction peak for both catalysts, assigned to the reduction of PtO<sub>x</sub> species. However, the peak for Pt-Zr/Al<sub>2</sub>O<sub>3</sub> appears at a significantly higher temperature (243 °C) than that for Pt/Al<sub>2</sub>O<sub>3</sub> (160 °C). An elevated reduction temperature typically signifies stronger metal-support interaction and improved metal dispersion.<sup>S1</sup>

The Zr 3d spectra (Fig. S1(c)) reveal an upward shift in the binding energy of Zr<sup>4+</sup> in Pt-Zr/Al<sub>2</sub>O<sub>3</sub> (182.4, 184.8 eV) compared to that in Zr/Al<sub>2</sub>O<sub>3</sub> (182.2, 184.6 eV), indicating that Zr loses electrons in Pt-Zr/Al<sub>2</sub>O<sub>3</sub>. Conversely, the Pt 4d spectrum of Pt-Zr/Al<sub>2</sub>O<sub>3</sub> (Fig. S1(d)) exhibits a shift to lower binding energy compared to Pt/Al<sub>2</sub>O<sub>3</sub>, suggesting electron enrichment on Pt. These complementary shifts provide clear evidence of an electron transfer from Zr to Pt, induced by their interaction.

**Fig. S1** Catalytic performance of Pt/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Pt-Zr/Al<sub>2</sub>O<sub>3</sub> (a); H<sub>2</sub>-TPR profiles of Pt/Al<sub>2</sub>O<sub>3</sub> and Pt-Zr/Al<sub>2</sub>O<sub>3</sub> (b); Zr 3d (c) and Pt 4d (d) in XPS spectra of Pt/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Pt-Zr/Al<sub>2</sub>O<sub>3</sub>. Reaction conditions: 0.4g catalyst, T = 600°C, 14.1 vol% ethylbenzene in N<sub>2</sub> (12 mL/min) and 5% O<sub>2</sub>/N<sub>2</sub> (30mL/min).

**Table S1.**  $X_{EB}$  and  $S_{ST}$  of Zr/Al<sub>2</sub>O<sub>3</sub>, Pt-Zr/Al<sub>2</sub>O<sub>3</sub>, and Fe-Zr/Al<sub>2</sub>O<sub>3</sub> catalysts at the 30th hour of reaction,  $C_{coke}$  after 56 hours of reaction, and Fe<sup>3+</sup> content of fresh Fe-Zr/Al<sub>2</sub>O<sub>3</sub>.

Catalyst	$X_{EB}$ (%)	$S_{ST}$ (%)	$C_{coke}^a$ (%)	Fe <sup>3+</sup> (%)

### The electron transfer within Fe-Zr on the surface of Al<sub>2</sub>O<sub>3</sub>

The catalytic performance of Fe/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Fe-Zr/Al<sub>2</sub>O<sub>3</sub> in the ODH of ethylbenzene under low-oxygen conditions is shown in Fig. S2(a). It can be observed that after a 12-hour induction period, Fe/Al<sub>2</sub>O<sub>3</sub> exhibits relatively stable activity. The  $X_{EB}$  is around 26–28%, and the  $S_{ST}$  lies between 96% and 98%. For Fe-Zr/Al<sub>2</sub>O<sub>3</sub>, the induction period is even longer: the  $X_{EB}$  increases gradually during the first 40 hours and then stabilizes, while the  $S_{ST}$  lies between 89% and 91%. Compared with Zr/Al<sub>2</sub>O<sub>3</sub> and Fe-Zr/Al<sub>2</sub>O<sub>3</sub>, Fe/Al<sub>2</sub>O<sub>3</sub> exhibits the lowest  $X_{EB}$  (26.8%), the highest  $C_{coke}$  (13.1%), and the highest  $S_{ST}$  (97.3%), as shown in Table 1. Due to the interaction between Fe and Zr, the Fe-Zr/Al<sub>2</sub>O<sub>3</sub> catalyst exhibits intermediate values: 39.2%  $X_{EB}$ , 90.0%  $S_{ST}$ , and 9.4%  $C_{coke}$ , suggesting that the introduction of ZrO<sub>2</sub> significantly improves the coke resistance of the Fe-based catalyst but limits the selectivity.

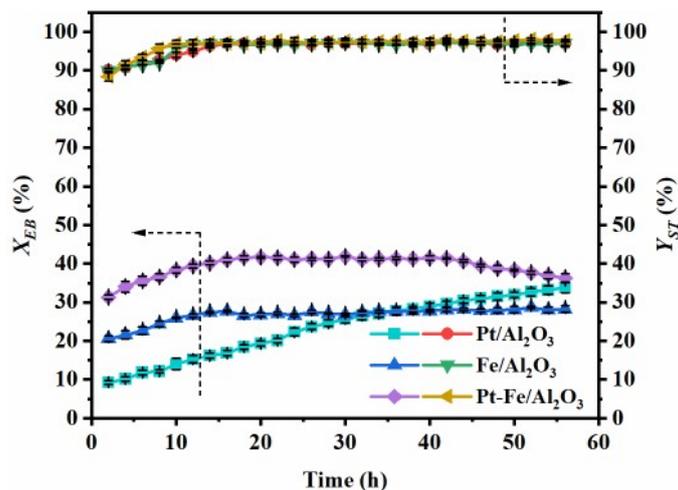

As shown in the H<sub>2</sub>-TPR profiles (Fig. S2(b)), both catalysts display three distinct reduction peaks. The low-temperature peak corresponds to the reduction of Fe<sub>2</sub>O<sub>3</sub> to Fe<sub>3</sub>O<sub>4</sub>, the medium-temperature peak to the reduction of Fe<sub>3</sub>O<sub>4</sub> to FeO, and the high-temperature peak to the reduction of FeO to metallic Fe. Notably, all three reduction peaks for Fe-Zr/Al<sub>2</sub>O<sub>3</sub> appear at higher temperatures than those for Fe/Al<sub>2</sub>O<sub>3</sub>, suggesting that the Fe-Zr interaction inhibits the reduction of iron oxide. In addition, the content of the Fe<sup>3+</sup> reduction peak in Fe-Zr/Al<sub>2</sub>O<sub>3</sub> (13%) is higher than that in Fe/Al<sub>2</sub>O<sub>3</sub> (8%).

The Zr 3d spectrum (Fig. S2(c)) shows that the binding energies of Zr<sup>4+</sup> in Fe-Zr/Al<sub>2</sub>O<sub>3</sub> are 182.1 eV and 184.4 eV, slightly lower than those in Zr/Al<sub>2</sub>O<sub>3</sub> (182.2 eV and 184.6 eV), indicating an increase in electron density on Zr in the bimetallic catalyst. In the Fe 2p spectrum of Fe-Zr/Al<sub>2</sub>O<sub>3</sub> (Fig. S2(d)), the binding energies of Fe<sup>2+</sup> (711.1 eV) and Fe<sup>3+</sup> (714.6 eV) shift to higher values relative to those in Fe/Al<sub>2</sub>O<sub>3</sub> (710.9, 714.5 eV), suggesting a decrease in electron density on Fe. These results clearly demonstrate that the Fe-Zr interaction induces electron transfer from Fe to Zr, reducing the electron density of Fe and increasing that of Zr. This variation in electron density influences the Fe<sup>3+</sup> content, as summarized in Table 1 and Table S1. The Fe<sup>3+</sup> content in Fe-Zr/Al<sub>2</sub>O<sub>3</sub> (34.1%, Table S1) is higher than that in Fe/Al<sub>2</sub>O<sub>3</sub> (31.7%, Table 1), consistent with the

H<sub>2</sub>-TPR results (Fig. S2(b)). Therefore, it can be concluded that the interaction between Fe and Zr not only facilitates the formation of Fe<sup>3+</sup> but also suppresses its reduction.

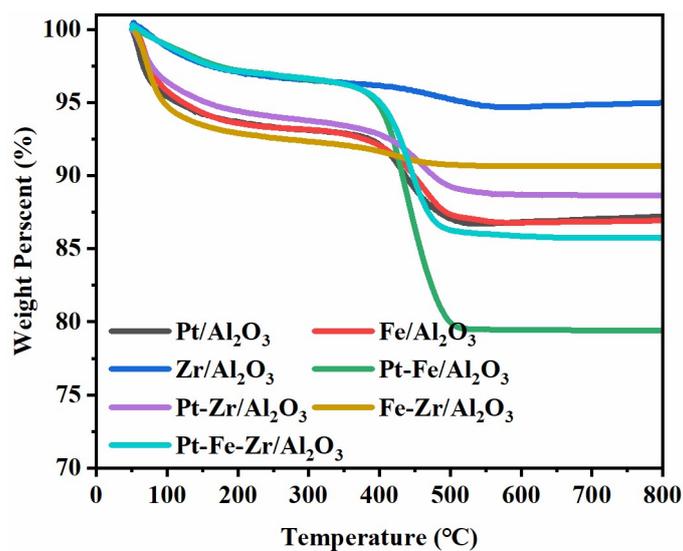

**Fig. S2** Catalytic performance of Fe/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Fe-Zr/Al<sub>2</sub>O<sub>3</sub> (a); H<sub>2</sub>-TPR profiles of Fe/Al<sub>2</sub>O<sub>3</sub> and Fe-Zr/Al<sub>2</sub>O<sub>3</sub> (b); Zr 3d (c) and Fe 2p (d) in XPS spectra of Fe/Al<sub>2</sub>O<sub>3</sub>, Zr/Al<sub>2</sub>O<sub>3</sub>, and Fe-Zr/Al<sub>2</sub>O<sub>3</sub>. Reaction conditions: 0.4g catalyst, T = 600°C, 14.1 vol% ethylbenzene in N<sub>2</sub> (12 mL/min) and 5% O<sub>2</sub>/N<sub>2</sub> (30mL/min).
