Fig. S7. Solvation structures for $\text{Li}(\text{EC}_c)_3(\text{PF}_6)$, $\text{Li}(\text{EMCc})_3(\text{EMCc})$, and $\text{Li}(\text{EMCc})_2(\text{PF}_6)$ solvation types obtained by SevenNet, compared with DFT results.¹ (a) RDFs (solid lines) of $\text{Li}-\text{O}_c$ and $\text{Li}-\text{O}_e$ and their CNs (dashed lines) for each solvation type. (b) Angular distributions of $\text{O}_c-\text{Li}-\text{O}_c$ and $\text{Li}-\text{O}_c-\text{C}_c$ angles for each solvation type. Example structures of each solvation type are illustrated in the inset.

Fig. S8. Radial distribution functions of Li, Na, and K cations between oxygens when solvated in EC molecules. Blue, orange, and green lines represent radial distribution functions from Li, Na, and K, respectively. The solid and dashed lines represent the results obtained from DFT calculations² and SevenNet, respectively.

Fig. S9. Variations in solvation environment among different types of solvents. (a) Representative SSIP, CIP, and AGG structures extracted from an MD trajectory of PC/1 M LiPF₆ (SSIP) and DMC/1 M LiPF₆ (CIP and AGG). (b) The average percentage of each Li solvation state of 1 M LiPF₆ salt concentration in four carbonates. The values are averaged across five independent production runs. The experimental dielectric constant at 298.15 K for each solvent is listed below its name.³

Procedure and analysis

Since the experimental density of EC/1 M LiPF₆ is unavailable, all simulations are performed starting with NPT equilibration to ensure a fair comparison, following the density-obtaining scheme in the main manuscript to determine the average density. Initial structures for NPT equilibration were created similarly with pure solvent NPT simulation (see section 2.2 in the main manuscript and Table S7 for the detailed information of the structure). Starting with 1.0-ns equilibration with a 2-fs timestep and a hydrogen atomic mass of 3 a.u., 0.4 ns of additional NPT simulation with a 1-fs timestep using the original hydrogen mass of 1 a.u. was conducted to obtain the initial configuration for the production run. Snapshots were saved every 100 fs, and a snapshot with a density closest to the average value over the last 0.2

ns of the NPT MD snapshots is selected as the initial structure of the NVT MD simulation (Equilibrated densities of PC, DMC, and DEC compositions are shown in Table S8. Equilibrated density of EC/1 M LiPF₆ is 1.461±0.001 g/cm³). Note that the densities are overestimated using SevenNet, which is present consistently at a high salt concentration regime in the EC/LiFSI system (Fig. S10). Subsequently, a 1-ns production run in the NVT ensemble is conducted for solvation analysis. The results are averaged from five independent simulations with different initial structures. The temperatures are set at 293 K, except for DMC (298 K) to match the experimental conditions. Snapshots are saved every 100 fs during a 1-ns production run, and the solvation states of Li ions are analyzed below and averaged over all Li ions and snapshots.

Li ions are classified into three solvation states: SSIP, CIP, and AGG (Fig. S9a). A Li ion is classified as SSIP if it has no counter anion in its first solvation shell. If it has only one counter anion in its first solvation shell with no other Li ions near the counter anion, it is designated as CIP. If the Li ion is part of a cluster with more than three ions, it is classified as AGG.

The distribution of Li solvation states in each solvent, along with their respective dielectric constants, is presented in Fig. S9b. SSIPs dominate the solvation state in cyclic carbonates, underscoring the strong dielectric shielding provided by these solvents. Conversely, in linear carbonates, fewer Li ions are fully solvated by the solvent and a larger portion of CIPs and AGGs is observed during simulation. The average CN of the PF₆⁻ counterion around Li⁺ is 0.04, 0.21, 0.72, and 1.01 in EC, PC, DMC, and DEC, respectively, reflecting distinct solvation behaviors between solvent types. The dominance of LiPF₆ ion pairs in solvents with low dielectric constants and their dissociation in high dielectric constant solvents have been demonstrated by infrared spectroscopy analysis,⁴ further supporting the trends observed in our

study. These results demonstrate that the pretrained potential effectively captures the dynamic variations in dielectric shielding between cyclic and linear solvents.

Fig. S10. Density obtained by SevenNet compared to experimental values^{3,5} with increasing LiFSI molar ratio in EC solvent system at 313 K.

Analysis of Fig. S10

The density of the EC/LiFSI electrolyte system shows that the calculated values using SevenNet qualitatively follow the experimental trend, systematically overestimating the experimental densities by 3–4% across the entire concentration range. Details in the initial structures are summarized in Table S10. It is worth noting that $x_{\text{LiFSI}} = 0.4$ corresponds to a concentration of 4.5 M, which is considered high for liquid electrolytes. The calculated (experimental^{3,5}) values are 1.367 (1.32), 1.472 (1.435), 1.572 (1.514), 1.649 (1.593), and 1.731 (1.669) g/cm³ for $x_{\text{LiFSI}} = 0, 0.1, 0.2, 0.3$, and 0.4, respectively.

Fig. S11. Schematic diagrams of placing Li ions within a cell with a top view along the x-axis. The shaded area indicates the possible location to place Li ions and the purple balls represent Li ions. (a) Method to place equal or less than 8 Li ions. The cubic box has dimensions of $(1/8)a \times (1/8)a \times (1/8)a$, where a is the length of the cell. (b) Method for placing up to 64 Li ions. The cubic box has dimensions of $(1/9)a \times (1/9)a \times (1/9)a$, where a is the length of the cell.

Fig. S12. Average CNs of Li contributed by EC and DMC solvents in EC/DMC (1 mol/kg LiPF_6) electrolyte at 298 K compared with experimental values⁶ and results obtained from other force fields (classical force fields with screened Coulomb interaction⁷ and APPLE&P⁸).

Fig. S13. MSD- τ plots (solid lines) and the linear regression results (dashed lines). The R^2 values from linear regression for each production run are shown in the legend. Gray boxes between 0.1 and 0.6 ns represent the linear regression region. Five independent runs are conducted for each system. (a) Results for Li ions and (b) PF_6^- anions in the PC/1 M LiPF_6 electrolyte. (c) Results for Li ions and (d) PF_6^- anions in the DMC/1 M LiPF_6 electrolyte. (e) Results for Li ions and (f) PF_6^- anions in the DEC/1 M LiPF_6 electrolyte. All MD simulations are conducted at experimental densities by applying the NVT ensemble.

Fig. S14. Similar or identical molecules with our solvent set in the training data. (a) All four structures in the training set that include DME molecules. (b) Representative similar molecules identified in the training set, featuring ether or ester groups, or containing five-membered ring structures.

Procedure to find the molecular units

Since our solvents share common elements (O, C, and H), we filter out structures that lack at least one of these elements, narrowing the dataset of relaxation trajectories from 145 923 compounds to 22 909 snapshots. For further analysis, we use snapshots from the final ionic step of the relaxation trajectory for each compound, totaling 1892 snapshots. In these structures, all metal elements are removed, leaving only metalloids and nonmetals. Bonds are assigned between atoms if the interatomic distance is less than the sum of the covalent radii of each atom plus 0.2 Å.⁹ This process segments a structure into clusters, each represented by its chemical formula. This enables us to identify molecules by their chemical formula from

all separated clusters and reveals that none of the solvents of interest are present in the training set, except for DME (Fig. S14a).

Although the exact molecules are absent from the training set, structurally similar molecules may be present. To investigate this, we perform a manual inspection of clusters with an atomic count similar to that of our solvent set. The range of the number of atoms is set with a margin of two. For instance, when investigating three-carbon molecules, clusters containing 6–14 atoms are inspected, as three-carbon solvents in our solvent set range from 8 atoms (VC) to 12 atoms (DMC). For four-, five-, and six-carbon molecules, clusters containing 10–18, 15–20, and 20–24 atoms are investigated, respectively. Structures containing ether and ester groups, as well as five-ring moieties similar to the ring substructure in EC are found (Fig. S14b).

Fig. S16. Structures from the training set containing (a) Li, Na, and K–O_c bonds and (b) Li and K–O_e bonds.

Procedure to find the molecular units

After the procedure outlined in Fig. S15, structures with Li, Na, or K–O_c bonds are filtered for Fig. S16a. Similarly, structures with Li, Na, or K–O_e bonds are filtered for Fig. S16b, though no Na–O_e bonds are identified.

Fig. S17. (a) The plot of latent vectors with principal component analysis (PCA). Circles represent PCA data points from the training set, while triangles represent PCA data points corresponding to the chemical moiety of C_{OF2H} from TFDMC. The gray, orange, red, blue, and green colors represent the total training set, C_{OF3} , C_{OF2H} , C_{OFH2} , and C_{OH3} moieties, respectively. (b) UMAP analysis on the training set and test set. The test set consists of five solvation shell structures: $Li(EC_c)_3PF_6$ (blue), $Li(EC_c)_4$ (orange), $Li(EMC_c)_2PF_6$ (green), $Li(EMC_c)_3(EMC_c)$ (red), and $Li(EMC_c)_3PF_6$ (purple). The gray circles represent the training set for SevenNet. The colored circles represent the structures in the training set that have the highest similarity to each test set structure. The Li environments are clustered in the black circle, and the O, C, and H environments are located outside.

Fig. S18. Training and validation results of fine-tuning procedure of SevenNet. The dashed lines indicate the MAEs of the fine-tuned potential with training epochs on the SevenNet training set filtered for the elements O, C, and H (19 072 structures). The solid lines demonstrate the learning curves of the validation set. Blue, orange, and green represent the energy, force, and stress MAEs, respectively.
