Effect of temperature on Ag/Zn-CNP activity. At 4°C, the potency of Ag/Zn-CNP was studied in the Tris-NaCl medium against all three strains. After 1 h of incubation about 1-log reduction was found and around 3-log reduction was observed after 24 h in *P. aeruginosa*. *S. aureus* showed a 2-log reduction after 3 hours and after 24 hours a 4-log reduction was detected. In the case of MRSA, no significant reduction was found after 3 h but at 24 h incubation a 2-log reduction in CFU was noticed (fig. S1 , C). However, Ag/Zn-CNP was able to significantly reduce the tested organism, indicating the Ag/Zn-CNP was able to hold antibacterial efficacy even at low temperature.

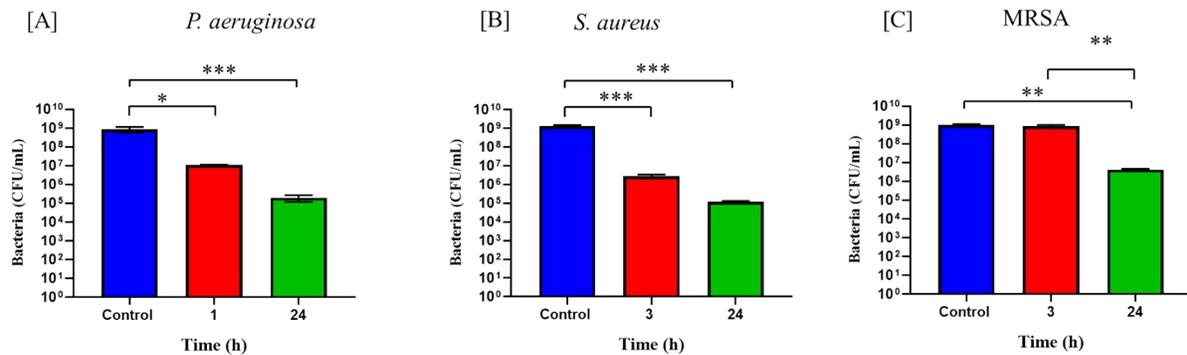

Figure S1 Effect of temperature on Ag/Zn-CNP activity. (A) A 1-log reduction in *P. aeruginosa* growth was observed at 1 h following supplementation with Ag/Zn-CNP and about ~3-log reduction was found after 24 h of incubation. (B) When *S. aureus* was treated with Ag/Zn-CNP a 2-log reduction was observed after 3 h and around 4-log reduction was noted after 24 h of incubation. (C) In MRSA group no significant reduction in growth was observed after 3 h treatment with Ag/Zn-CNP whereas after 24 h, a ~2-log reduction in growth was observed. (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$).

Cytotoxicity study on Ag/Zn-CNP. The Ag/Zn-CNP cytotoxicity effect on macrophage cells was studied at an increasing concentration from 0-400 $\mu\text{g}/\text{mL}$. On day-1 no significant differences were observed at 4 and 6 $\mu\text{g}/\text{mL}$ showing that no detectable cytotoxicity to cells, indicating preserved cell viability (Fig. S2 A). A significant decrease in viability was noted at 30 $\mu\text{g}/\text{mL}$ and at higher concentration (100 and 400 $\mu\text{g}/\text{mL}$) complete loss of viability was observed (Fig. S2 C). Hence. The cells were able to tolerate low concentration but Ag/Zn-CNP at higher doses are strongly cytotoxic to the cells. At 6 $\mu\text{g}/\text{mL}$ on day 3 showed a significant ($p>0.01$) (Fig. S2 B) decrease in metabolic activity of cells but no death cells were noted (Fig. S2 C) . But at 30 $\mu\text{g}/\text{mL}$ significant loss of viable (green) signal was observed and complete loss of cells were noted at 100 and 400 $\mu\text{g}/\text{mL}$.

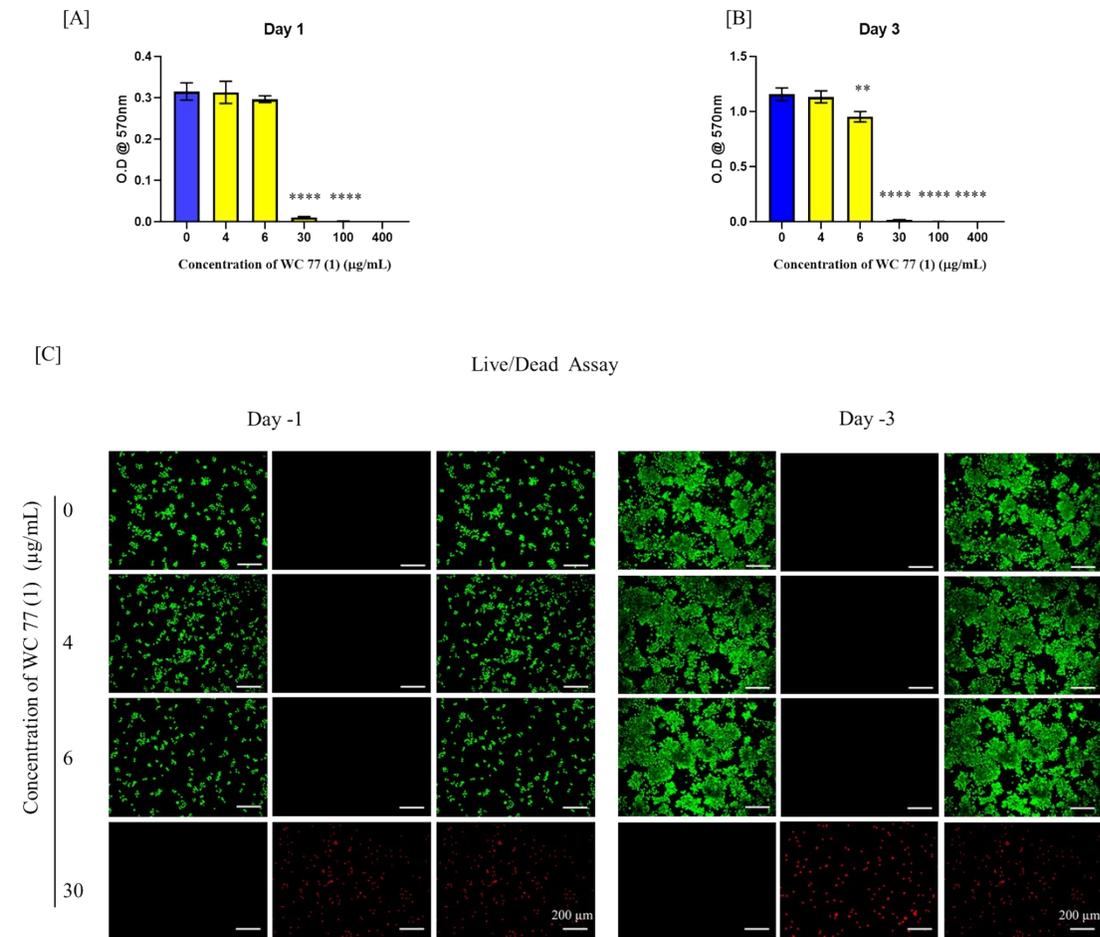

Figure S2 Cytotoxicity study on macrophage (RAW 264.7) cells. [A] Cell metabolic activity was assessed and the response to Ag/Zn-CNP was quantified using MTT assay on day 1 no significant change in cell metabolic activity was observed when the macrophage cells are treated up to 6 $\mu\text{g}/\text{mL}$. A complete reduction was observed when the concentration was increased more than 30 $\mu\text{g}/\text{mL}$. (B) On day a significant reduction ($p<0.01$) in cell metabolic activity was observed in

macrophage cells when treated with 6 $\mu\text{g}/\text{mL}$ of Ag/Zn-CNP and a complete reduction ($p < 0.0001$) was observed when treated with more than 30 $\mu\text{g}/\text{mL}$. [C] Live/Dead assay on day 1 and day 3. (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, and **** $p < 0.0001$).

Table S1. Tabulated adsorption energies (eV) of all the configurations simulated using DFT calculations. Hydrogen peroxide (H_2O_2) and its dissociated forms (H/OO/H, H/OOH, HO/OH) are adsorbed on the {111}, {110} and {100} surfaces of cerium dioxide at different surface compositions. The label Ag represents the presence of a surface Ag_3 cluster. The label Zn represents that a surface Ce atom has been replaced with a Zn atom.

Surface Plane	Surface Stoichiometry	Adsorbate	Surface Composition	
			Zn	Ag/Zn

Figure S3. Density Functional Theory calculations and Configurations. Adsorption energies of molecular H₂O₂ and its dissociation products (HO/OH, H/OOH, H/OO/H) onto the {111}, {110} and {100} surfaces of stoichiometric Zn@CeO₂ and Zn/Ag@CeO₂, oxygen deficient Zn@CeO_{2-x}(SL) and Zn/Ag@CeO_{2-x}(SL) where the oxygen vacancy is positioned in the top layer, and oxygen deficient Zn@CeO_{2-x}(SSL) and Zn/Ag@CeO_{2-x}(SSL) where the oxygen vacancy is positioned in the subsurface layer. All values are calculated using DFT simulations. Ce, O, Ag and H as green, red, grey, and white spheres, and oxygen vacancies as blue squares.

TableS2. List of configurations with details of geometric and magnetic symmetry of each configuration alongside the number of Ce³⁺ and the nature of the adsorbed species after minimization using DFT calculations. Where attempts to stabilize certain configurations have been unsuccessful, the label n/a is used. All the configurations are symmetric in terms of their geometry and distribution of Ce³⁺

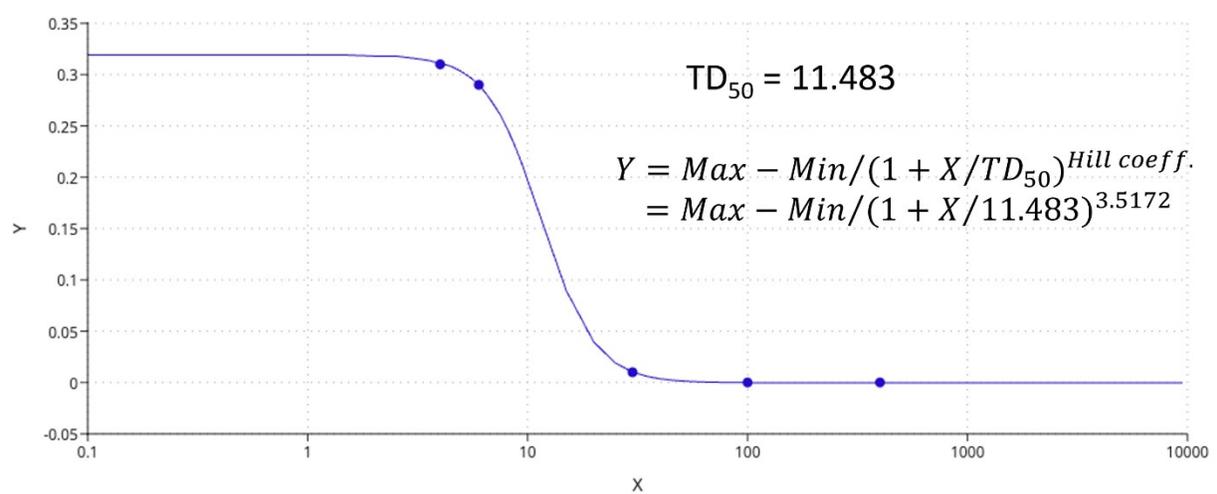

Figure S4. Regression analysis of the macrophage response to Ag/Zn-CNP on day 1 of culture and Calculation of Therapeutic Index. The therapeutic index (TI) measures the safety margin of a novel product by comparing the dose that produces a desired effect to the dose that causes toxicity. The TD_{50} of Ag/Zn-CNP was determined by regression analysis of macrophage culture response to Ag/Zn-CNP (culture time: 1 day; Fig. S2) and calculated as 11.483 $\mu\text{g}/\text{mL}$. In the absence of surface fouling biomolecules, the MIC (or ED_{50}) of *P. aeruginosa* was 4 $\mu\text{g}/\text{mL}$, and 6 $\mu\text{g}/\text{mL}$ for both *S. aureus* and MRSA. Therefore, a TI (TD_{50}/EC_{50}) of 2.87 was calculated for *P. aeruginosa* and 1.91 for both *S. aureus* and MRSA. Similarly, using an EC_{50} for RV14 and VSV of 20 $\mu\text{g}/\text{ml}$ and 150 $\mu\text{g}/\text{ml}$ (derived from results presented in Fig. 2), yielded TIs of 0.574 and 0.077, respectively. However, for bacterial studies performed in the presence of biomolecules, it was noted that the MIC of *P. aeruginosa* increased to 30 $\mu\text{g}/\text{mL}$ and the MIC of *S. aureus* and MRSA both increased to 400 $\mu\text{g}/\text{mL}$. Thus, it is indicated that when in the presence of biomolecules, the effective therapeutic dose is higher than the concentration which causes toxicity to host cells. This highlights a further need for research developing measures that minimize biofouling or that otherwise limit physicochemical processes inducing host toxic responses prior to the material's use as an antimicrobial, *in vivo*.
