1. General information:

All reactions were performed with the commercially available starting materials without any further purifications. Zerumbone was isolated from *Zingiber zerumbet* (L) Smith rhizomes purchased from Siddha Medicinal Plants Garden, Salem, India. Proton nuclear magnetic resonance (¹H NMR) spectra were recorded on a Bruker BBFO (500 MHz) spectrometer at SRM University and Gandhigram University. Chemical shifts were recorded in parts per million (ppm, δ) relative to chloroform ($\delta = 7.26$, singlet). ¹H NMR splitting patterns are designated as singlet (s), doublet (d), triplet (t), quartet (q), doublet of doublets (dd), multiplet, (m), broad singlet (bs), etc. Carbon nuclear magnetic resonance (¹³C NMR) spectra were recorded on a Bruker BBFO (101 MHz) spectrometer. ¹³C NMR data are reported with the solvent peak ($\text{CDCl}_3 = 77.16$) as the internal standard. High-resolution mass spectral analysis (HRMS) was performed on the Bruker Impact HD mass spectrometer. Single crystal X-ray diffractometer (SCXRD) analysis was carried out using Bruker, D8 Quest (NRC). Analytical thin-layer chromatography (TLC) was carried out on a Merck 60 F254 pre-coated silica gel plate (0.2 mm thickness). Visualization was performed using a UV lamp.

2. Extraction and isolation procedure for zerumbone:

Zerumbone **1** is a form of sesquiterpenes isolated from *Zingiber zerumbet* (L) Smith rhizomes. Further rhizomes were cleaned and chopped into small pieces. It was dried at room temperature for three days and powdered. One kilogram of the powdered rhizomes is extracted with methanol (3L) at room temperature, overnight with occasional shaking. The extraction is filtered and concentrated under reduced pressure to get 100 g of crude. This was further subjected to silica gel column chromatography using a hexane and ethyl acetate system. The desired Zerumbone **1** was eluted around 8:2 (Hexane: Ethyl acetate) and obtained **16 g of Zerumbone (1)**

3. General procedure for the synthesis of *N*-hydroxyimoyl chloride

The compound **3** was dissolved in H₂O followed by the addition of Na₂CO₃ (0.7 equiv), NH₄OH.HCl (1 equiv) reflux, 2 h. The reaction mixture was allowed to stir at 80 °C. The reaction completion was monitored by TLC chromatography (2-5 h). After completion, the reaction was extracted with ethyl acetate (3 x 10 mL). The combined ethyl acetate layer was dried over anhydrous sodium sulfate and concentrated under reduced pressure to get a crude compound. The obtained crude **4** was used for the next step without further purification. Obtained aldoximes are further dissolved in MeCN: H₂O followed by the addition of Oxone (1.1 equiv) and NaCl (1.1 equiv). The reaction mixture was stirred at room temperature for 2-14 hours. After completion of the reaction the reaction mixture was concentrated in a vacuum and extracted with ethyl acetate (3 x 10 mL). The combined ethyl acetate layer was dried over anhydrous sodium sulfate and concentrated under reduced pressure to get a crude compound. The obtained crude was purified using column chromatography by eluting hexane/ethyl acetate to afford the desired product. **5a-5i**

16. Mechanism

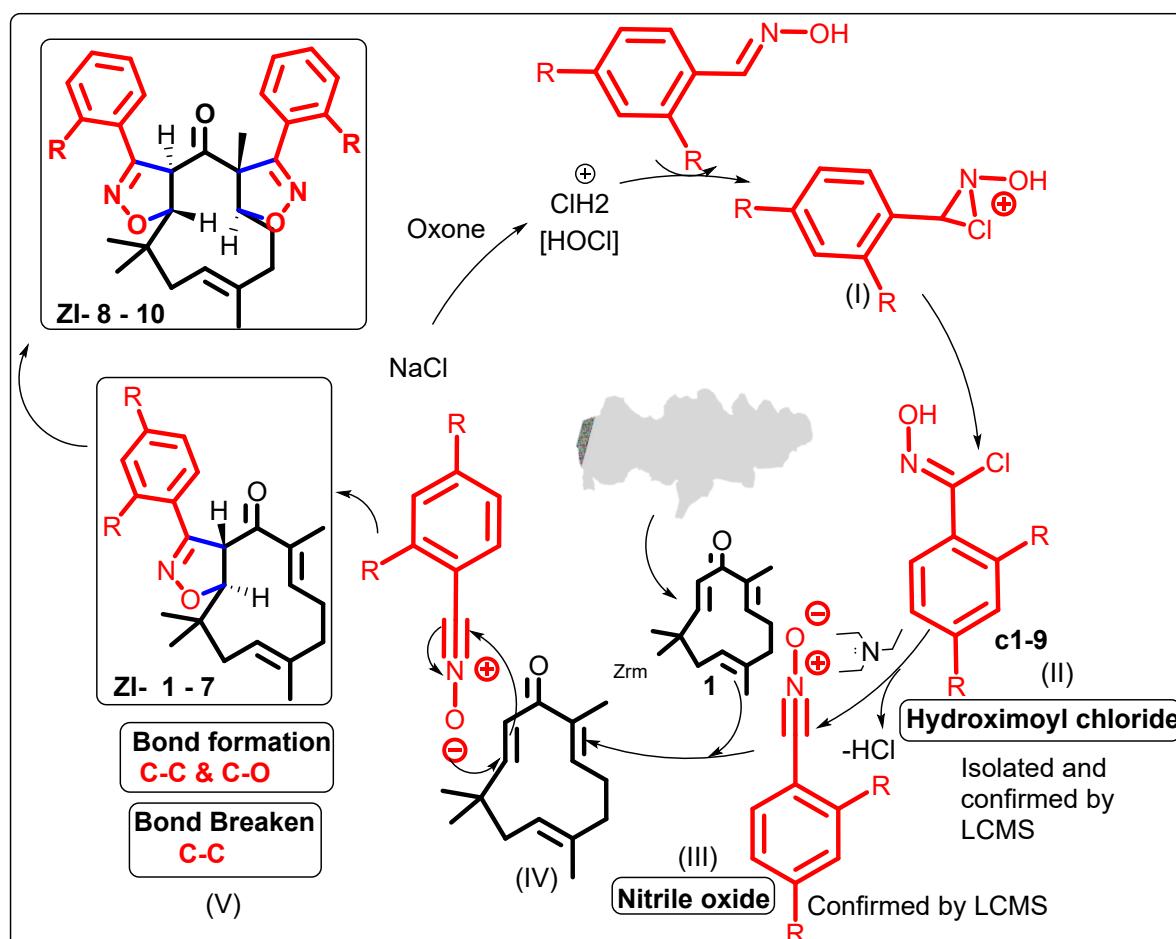

Mechanism -1

Scheme 4: Plausible reaction mechanism for Zerumbone fuced Spirocycle compounds

Transitioning towards spirocycles synthesis involves a stepwise progression starting with a straightforward addition reaction between isatin and L-proline, yielding a hemiaminal intermediate (I). Upon the removal of water, this intermediate transforms into an oxazolidinone (II). Subsequently, an intramolecular cyclization event occurs, facilitating decarboxylation and leading to the generation of an azomethine ylide (III). This reactive intermediate undergoes further cyclisation processes through subsequent chemical transformations with zerumbone (IV), ultimately yielding the desired product **ZS-1 (V)**. This sequential series of reactions underscores a strategic approach toward the synthesis of intricate spirocycles, showcasing the intricate.

Mechanism -2

Scheme 5: Plausible reaction mechanism for Zerumbone fused Isoxazoline compounds

An outline of the catalytic cyclization mechanism is given in Scheme 4. First, a reaction between NaCl and Oxone produces hypochlorous acid, the active chlorine species. The production of the chlorine ion results from this hypochlorous acid's interaction with the aldoxime. Following this, the alkene and chlorine ion engage in an opening reaction (I) that yields N-hydroxybenzimidoyl chloride (II) (confirmed by LC-MS). In addition, triethylamine affords nitrile oxide (III) (confirmed by LC-MS) with the elimination of HCl. Subsequent chemical changes aid in the cyclization process (IV), which then proceeds further and culminates in beta elimination to produce the desired isoxazoline molecule ZI-1 to ZI-10 (V). This sequential process demonstrates the complexity of the cyclization pathway and emphasizes how crucial each reactive intermediate is to producing the desired end product.

17. Computational details

Methodology:

All quantum chemical calculations were carried out using the Gaussian 16 software suite¹, employing density functional theory (DFT) as the computational methodology. The B3LYP hybrid functional²⁻⁴, renowned for its accuracy and computational efficiency, was utilized in conjunction with the 6-31G(d,p) basis set for energy minimization^{5,6}. To improve the precision of the energy calculations and account for long-range interactions, the more sophisticated

triple-zeta valence polarized def2-TZVP basis set was employed⁷. This was complemented by Grimme's D3 dispersion corrections, ensuring highly accurate energy predictions and a robust treatment of non-covalent interactions⁸. Geometrical optimizations were conducted without any symmetry or constraints, allowing for the attainment of true minimum energy configurations. The polarized continuum model (PCM) was applied to account for solvent effects, effectively simulating solvent polarity⁹. Methanol was chosen as the solvent for reactions involving C-nucleophiles, while N,N-dimethylformamide (DMF) was used for reactions with O-nucleophiles. These analyses were critical in confirming that the structures corresponded to authentic minima or transition states on the potential energy surface (PES). Additionally, intrinsic reaction coordinate (IRC) calculations were systematically conducted to validate that the transition states connected the correct reactants and products, providing a comprehensive understanding of the reaction mechanism.

Interaction of 1 with Nucleophiles

The zerumbone **1** was optimized using various initial structural models to determine its ground state geometry accurately. The nucleophiles interact with **1** at the C2-C3 and C10-C11 double bonds. For each nucleophile, interactions are considered at both double bonds in two distinct orientations, as illustrated in Figure S67. Specifically, the nucleophile is allowed to approach **1** from both the top and bottom of the ring at the C10-C11 double bond. This methodology is consistently applied to both C- and O-nucleophiles at both double bonds. In doing so, we systematically explore all possible interaction configurations, ensuring that no potential conformational pathways are overlooked.
