In equation 1 below, ΔG(prd.) is summation of the Gibbs free energy of all compounds on the product side, i.e., for method ii: $G(Ca^{2+}.ligand^{n-}) + 12G(H_2O)$ and ΔG(react.) is summation of Gibbs free energy of all reactant species i.e., $G(Ca^{2+}.6H_2O) + G(ligand^{n-})$. This applies for other reaction equations related to method i and method iii. Hence, for reaction equation i: $G(Ca^{2+}.chelate^{n-}) + 6G(H_2O) - G(Chelate^{n-}) - G(Ca^{2+}.6H_2O)$ and the same for reaction equation iii: $G((n-2)Na^+.Ca^{2+}.chelate^{n-}) + G(2Na^+.6H_2O) - G(Ca^{2+}.6H_2O) - G(Chelate^{n-}.nNa^+)$. We included this in the text (in blue right after equation 1 and 2) and with more detailed in the SI.

Energy Decomposition Analysis (EDA)

In the Energy Decomposition Analysis (EDA) approach, the total interaction energy between the two fragments at any specific molecular structure is divided into its various components including ΔE_{Pauli} that is the interaction between the occupied molecular orbitals and is responsible for the steric repulsion, ΔE_{elstat} that is the classical electrostatic interaction between the two fragments. ΔE_{steric} is the sum of ΔE_{Pauli} and ΔE_{elstat}. ΔE_{oi} is the orbital interaction that accounts for the charge transfer between the HOMO and LUMO of the two fragments (covalent interaction); finally, ΔE_{disp} accounts for the dispersion energy due to the van der Waals and long range attractions. ΔE_{int} is the sum of the electrostatic, Pauli, and orbital interactions plus dispersion contribution. We calculate EDA between Ca^{2+} and the rest of molecular complex.

$$\Delta E_{int} = \Delta E_{Pauli} + \Delta E_{elstat} + \Delta E_{oi} + \Delta E_{disp}$$

Table S6: EDA results (in kcal/mol) for neutralized ligands with Na^{+} counterion: the interaction energies are calculated between Ca^{2+} and the rest of molecular complex ($Na^{+}(n-2).Ligand$)

Conclusion based on Tables S5 – S7, neutralization is basically an inherent physical characteristic of counterion association.

The effect of water concentration

$K_{exp} = [CaL]/([Ca \cdot 6H_2O][L \cdot 6H_2O])$

$K_{ii} = ([CaL][H_2O]^{12})/([Ca \cdot 6H_2O][L \cdot 6H_2O])$

$K_{ii} = K_{exp} \cdot [H_2O]^{12}$

Therefore, to calculate K_{exp} from ΔG_{ii} one should calculate:

$K_{ii} = \exp(-\Delta G_{ii}/RT)$

And then, correct K_{ii} to obtain K_{exp}:

$K_{exp} = K_{ii} \cdot [H_2O]^{(-12)}$

Or directly from ΔG_{ii}:

$K_{exp} = \exp(-\Delta G_{ii}/RT) \cdot [H_2O]^{(-12)}$

In the logarithmic form:

$\log(K_{exp}) = -(\Delta G_{ii},1M)/RT\ln10 - 12 \log[H_2O]$

In summary, first ΔG_{ii} is calculated by including all the present water molecules. Second, to obtain $\log(K_{exp})$, the term $12\log[H_2O]$ has to be considered to correct K_{ii}.

Similarly, for reaction i one should calculate ΔG_i by taking into account the 6 water molecules on the products side and later subtract the term $6\log[H_2O]$ to obtain $\log(K_{exp})$:

$\log(K_{exp}) = -(\Delta G_i,1M)/RT\ln10 - 6 \log[H_2O]$

Table S8: Reaction i with removing 6 log[H_2O] in order to obtain a closer correlation with respect to the experimental logK values.

Calculation of the conversion factor of ΔG 1atm→1M

Free energies calculated with Gaussian using ideal-gas partition functions are referenced to 1 atm, whereas the experimentally determined K in solution is referenced to a concentration of 1 M. The free energy of standard-state change must be considered. This term has no effect when the number of moles of reactants and products is the same, but this is not the case in equation 1. For each species, there is a term

$\Delta G(1atm \rightarrow 1M)$ = G(1M) - G(1atm) = -RTln(C_1M/C_1atm) =

= -RT ln(1molL^(-1))/((1atm/(0.0820atmLK^(-1) mol^(-1) 298K))) ≅ **1.89kcal·mol^(-1)**

Thus, the free energy of reaction 1 for a 1 M standard state is:

ΔG1,1M = 12[G(H2O,1atm)+$\Delta G(1atm \rightarrow 1M)$] + [G(CaL,1atm)+$\Delta G(1atm \rightarrow 1M)$] - [G(Ca·6H2O,1atm)+$\Delta G(1atm \rightarrow 1M)$] - [G(L·6H2O,1atm)+$\Delta G(1atm \rightarrow 1M)$] =

ΔG1,1atm+11$\Delta G(1atm \rightarrow 1M)$

Addition of a constant term does not change the trade-off and hence the R^2 value.

Table S10. Addition of 1atm to 1M correction results in smaller logK values than previously calculated with the same R^2 but different intercept.

Reaction iii and associated sodium-ligand concentration

Reaction iii is a metal-exchange reaction mediated by the ligand. Therefore, the calculated free energy is not directly related to the logK of the complex $Na_{n-2}CaL$, but rather to the free-energy difference between the complexes $Na_{n-2}CaL$ and Na_nL. Then, there are two reactants and two products with no release of water molecules. The free-energy difference at 1 atm and 1 M would be the same, and thus:

$\Delta G_{iii} = G(Na_{(n-2)}CaL) + G(2Na\cdot6H_2O) - G(Na_nL) - G(Ca\cdot6H_2O) = \Delta G(f,Na_{(n-2)}CaL) - \Delta G(f,Na_nL)$

$\Delta G_{iii} = -RTln(K(Na_{(n-2)}CaL) / K(Na_nL))$

$log[K(Na_{(n-2)}CaL)] = -(\Delta G_{iii})/(RTln10) + log(K(Na_nL))$

The values of $log(K(Na_nL))$, which are considerably small due to the very weak binding interaction with the ligands, were reported in previous experimental investigations in literature.[50-57]

Table S12. The experimental logK values for Na_nL ionic species

Ligand	logK$_{iii}$	Exp. logK(Na_nL)	log[K($Na_{(n-2)}CaL$)]
EDTA	14.01	1.6	15.61
DTPA	13.08	2.5	15.58
MGDA	10.22	1.8	12.02
NTA	9.31	2.1	11.41
GLDA	7.80	2.5	10.30
EDDM*	9.21	0.5	9.71
