## 1 Materials and reagents

Ferric nitrate nonahydrate ( $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ ), Rhodamine B ( $\text{C}_{28}\text{H}_{31}\text{ClN}_2\text{O}_3$ ), Methylene blue ( $\text{C}_{16}\text{H}_{18}\text{ClN}_3\text{S}$ ), Congo red ( $\text{C}_{32}\text{H}_{22}\text{N}_6\text{Na}_2\text{O}_6\text{S}_2$ ), Methyl Orange ( $\text{C}_{14}\text{H}_{14}\text{N}_3\text{NaO}_3\text{S}$ ) were purchased from Sinopharm Chemical Reagent Co., Ltd. Urea ( $\text{CH}_4\text{N}_2\text{O}$ ), Ammonium Fluoride ( $\text{NH}_4\text{F}$ ), 4-nitrophenol (4-NP), 2-nitrophenol (2-NP), 3-nitrophenol (3-NP) and sodium borohydride ( $\text{NaBH}_4$ ) were purchased from Shanghai McLean Biochemical Technology Co., Ltd. and used directly without further purification. Copper foam (CF) was purchased from Kunshan Zuanyan Metal Technology Co., Ltd.

## 2 Characterization

Nitrogen adsorption/desorption isotherms were obtained at 77 K on an accelerated surface area and porosimetry system (ASAP2460-4MP, USA) to measure the surface area of the material using the Brunauer-Emmett-Teller (BET) method. Before analysis, the samples were outgassed under dynamic vacuum at 80°C for 5 h. Raman spectra were collected on an in Via instrument with a  $\lambda = 532$  nm excitation laser. All the reaction solutions were diluted with deionized water and their UV-visible absorption spectra were measured by UV-1000. X-ray diffraction (XRD) was performed using a SmartLab 9KW Advance diffractometer. XRD patterns were recorded with  $\text{Cu K}\alpha$  radiation ( $\lambda = 0.154$  nm, 40 kV, 30 mA) in the  $10\text{-}80^\circ$   $2\theta$  range with a  $0.02^\circ$  of  $2\theta$  step. Phase identification was made by comparison with the ICDD database. Scanning electronic microscopy (SEM) images were obtained using Regulus 8100. Micrographs from Transmission Electron Microscopy (TEM) were conducted on a HT-7700. X-ray photoelectron spectroscopy (XPS) was performed with an Krayos AXIS Ultra DLD (UK), using  $\text{Al K}\alpha$  radiation (1486.6 eV) at a pressure of  $9.8 \times 10^{-10}$  Torr. The peak positions were internally referenced to the C 1s peak at 284.8 eV. The Casa XPS software package was used for data analysis.

### **3 Preparation of the $\beta$ -FeOOH@CF catalyst**

$\beta$ -FeOOH@CF foam catalysts were prepared by growing  $\beta$ -FeOOH on monolithic copper foam substrates via hydrothermal synthesis. First, commercial foam copper CF was cut into circular discs (60 PPI, diameter 3.5 cm, thickness 0.5 cm) and immersed in a 1 M hydrochloric acid solution for 10 minutes of ultrasonic treatment to remove the surface oxide layer. Subsequently, the samples were repeatedly rinsed with deionized water until the filtrate became neutral (pH = 7). They were then placed in acetone and sonicated for 10 minutes to remove organic contaminants and grease. Finally, after thorough rinsing with deionized water, excess surface moisture was blotted with filter paper, and the samples were placed in an 80 °C vacuum drying oven until completely dry.

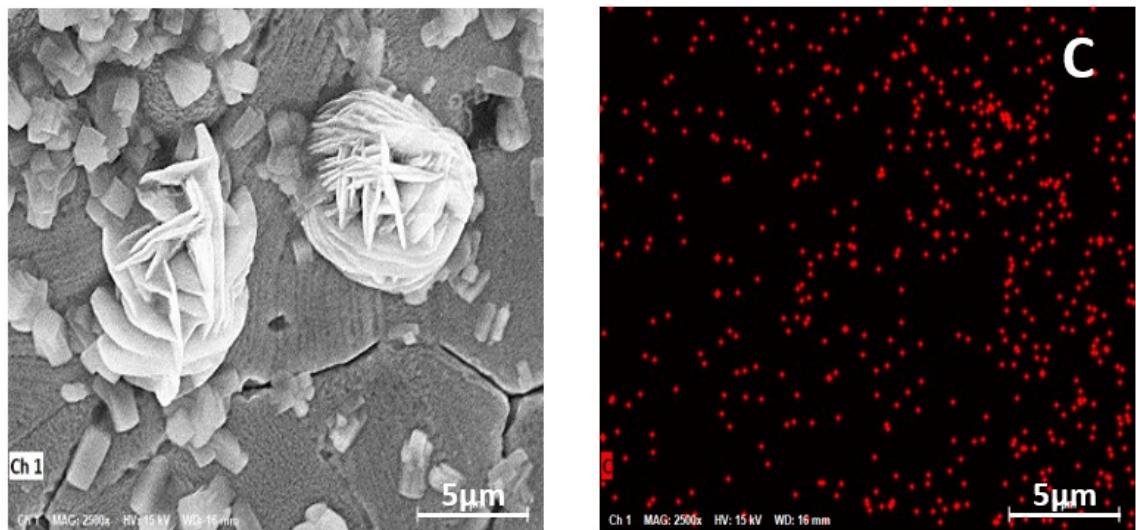

Place the pretreated foam copper at an angle inside a 200 mL high-pressure reactor lined with polytetrafluoroethylene. Separately, dissolve  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  (1.2 g), urea,  $\text{NH}_4\text{F}$  and in a molar ratio of 3:25:8 using 80 mL of deionized water. Transfer this precursor solution into the reactor, ensuring the foam copper is fully submerged. Heat-treat the reactor at 100°C for 8-14 hours. After reaction completion and natural cooling to room temperature, carefully remove the copper foam coated with the product. Repeatedly rinse with deionized water to remove loosely adsorbed ions and impurities, then dry in an 80°C vacuum oven for 12 hours to obtain the final  $\beta$ -FeOOH@CF product.

### **4 Catalytic reduction of nitrogen-containing contaminant**

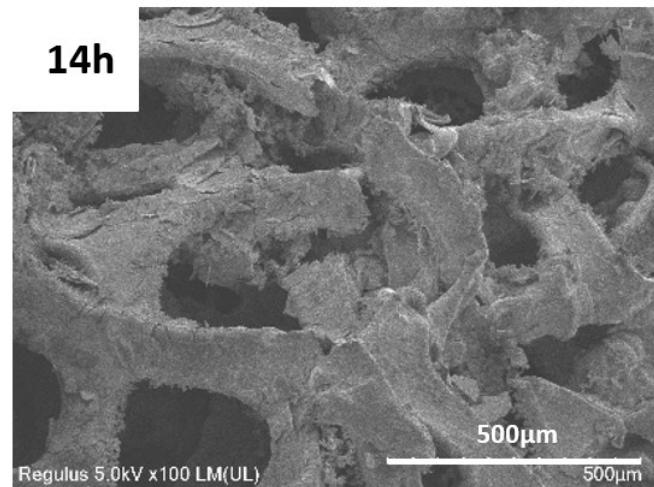

In experiments on the catalytic reduction of nitrogen-containing contaminants, we selected 4-nitrophenol (4-NP), 3-nitrophenol (3-NP), 2-nitrophenol (2-NP), methyl orange (MO), Congo red (CR), Rhodamine B (RhB) and methylene blue (MB) as representative nitrogen-containing organic compound models to evaluate the catalytic performance of the continuous-flow system. Flow rate was controlled by adjusting external pressure to optimize conversion rates and

reaction times for nitrogen-containing contaminants. All substrates (4-NP, 3-NP, 2-NP, MO, CR, RhB and MB) were maintained at a concentration of  $5.0 \text{ mmol}\cdot\text{L}^{-1}$  in aqueous solution, with a total volume of 20 mL. For the reduction of nitroaromatics and azo dyes, the  $\text{NaBH}_4$  dosage was uniformly set at 200 equivalents. The reduction of nitroaromatics and azo dyes to corresponding aniline products was monitored using UV-visible spectrophotometry. Additionally, the fading of the reaction solution served as an intuitive indicator of reaction completion. Typically, the conversion rate was calculated based on the intensity change of the characteristic absorption peak of the 4-nitrophenol anion, using the formula  $(C_0 - C_t)/C_0$ , where  $C_0$  and  $C_t$  represent the concentrations of 4-NP measured by UV-visible spectroscopy at the initial time and at reaction time  $t$ , respectively.
