1. General Information

Unless otherwise stated, all glassware was flame-dried before use and all reactions were performed under an atmosphere of argon. All solvents were distilled from appropriate drying agents prior to use. All reagents were used as received from commercial suppliers unless otherwise stated. Reaction progress was monitored by thin layer chromatography (TLC) performed on aluminum plates coated with silica gel F254 with 0.2 mm thickness. Chromatograms were visualized by fluorescence quenching with UV light at 254 nm or by staining using potassium permanganate. Flash column chromatography was performed using silica gel 60 (230-400 mesh, Merck and co.). Neat infrared spectra were recorded using a Perkin-Elmer Spectrum 100 FT-IR spectrometer. Wavenumbers (ν_{max}) are reported in cm^{-1} . Mass spectra were obtained using a Bruker maXis UHR-TOF (QQ-TOF) spectrometer, using electrospray ionization (ESI) or an Agilent 7200B GC/Q-TOF spectrometer, using electron ionization (EI). All ^1H NMR and ^{13}C NMR spectra were recorded using a Bruker AV-400 or AV-600 spectrometer at 300 K. Chemical shifts are given in parts per million (ppm, δ), referenced to the solvent peak of CDCl_3 defined at $\delta = 7.26$ ppm (^1H NMR) and $\delta = 77.16$ (^{13}C NMR). Coupling constants are quoted in Hz (J). ^1H NMR splitting patterns are designated as singlet (s), doublet (d), triplet (t), quartet (q), heptet (hept), as they appeared in the spectrum. If the appearance of a signal differs from the expected splitting pattern, the observed pattern is designated as apparent (app). Splitting patterns that could not be interpreted or easily visualized are designated as multiplet (m) or broad (br).

3. Experimental

3.1. Preparation of iodonium reagents

Compounds were prepared using a modified version of a reported procedure.¹

To a cooled solution (0°C) of the corresponding diacetoxyiodoarene (1.0 eq.) in chloroform (CHCl_3 , 2 M), the acid (1.2 eq.) was slowly added, and the resulting mixture was allowed to warm to 23°C . After 1 h, water (1.0 mL for 1.00 mmol of starting diacetoxyiodoarene) was added, and the mixture was cooled to 0°C . After 3 h at 0°C , a precipitate had formed and the mixture was filtered. The precipitate was washed with CHCl_3 , water and pentane. The obtained solid was crushed to a powder and the washing steps were repeated in the same order twice. The resulting solid was dried under high vacuum (10^{-2} – 10^{-3} mbar) for at least 5 h to afford the dicationic iodonium reagent as a bright-yellow powder.

3.2. General procedures

3.2.1. General procedure 1 (GP1): Preparation of Weinreb amides

Triethylamine (2.0 eq.) was slowly added at 0 °C to a stirred suspension of *N,O*-dimethylhydroxylamine hydrochloride (1.0 eq.) in DCM (0.1 M). The corresponding acyl chloride (1.0 eq.) was then slowly added to the solution. The resulting mixture was allowed to warm to room temperature over 16 h before stopping the reaction by addition of a saturated aqueous solution of NaHCO₃. The two layers were separated, and the organic phase was washed with 1 M HCl and brine. The organic phase was dried over sodium sulfate before being concentrated in vacuo. The obtained products were used without further purification.

3.2.2. General procedure 2 (GP2): Weinreb amides for the preparation of 1,1-disubstituted olefins

Step 1: A modified procedure for hydroarylation was used.² Under argon, a flame-dried Schlenk flask was loaded with Pd(Ph₃)₄ (0.05 eq.), the corresponding boronic acid (1.2 eq.) and 6-heptynoic acid (1.0 eq.). Lastly, dioxane (0.3 M) and acetic acid (0.1 eq.) were added. The mixture was heated at 80 °C for 15 h. After cooling to room temperature, dioxane was removed under reduced pressure. Then, the crude material was dissolved in EtOAc and passed through a short pad of Celite. The solution was concentrated and the crude material obtained was immediately used for the next step without further purification.

Step 2: The crude material was dissolved in anhydrous DCM (0.3 M) and 1,1'-carbonyldiimidazole (1.3 eq.) was added in portions. Strong gas evolution was observed immediately after addition and the solution was subsequently stirred at room temperature for 1 h. Then, *N,O*-dimethylhydroxylamine hydrochloride (2.0 eq.) was added and the resulting suspension was stirred at room temperature for 16 h. To stop the reaction, 1M HCl was added and the aqueous phase was extracted with DCM (3 x 10 mL). The organic phase was washed with a saturated solution of NaHCO₃ (3 x 10 mL) and then with brine (1 x 10 mL). The organic phase was dried over MgSO₄ and the solvent was removed under reduced pressure. The crude material was purified by column chromatography (heptane/EtOAc = 97:3 to 90:10), yielding the desired Weinreb amides.

3.2.3. General procedure 3 (GP3): Preparation of ketones from Weinreb amides

Step 1: Preparation of Grignard

A THF solution of the bromide was slowly added to a suspension of magnesium turnings (2.0 eq.) in THF (total targeted molarity 1 M). After complete addition of the bromide solution, the mixture was stirred for a further 2 h until most of the magnesium had dissolved. The concentration of the Grignard solution was determined by titration with I₂ before use.

Step 2: Preparation of ketones

In a separate flask, the corresponding Weinreb amide was dissolved in THF (0.4 M) and cooled to 0 °C. A solution of Grignard reagent was then added dropwise. The resulting mixture was allowed to warm to room temperature over 16 h before stopping the reaction by addition of a saturated aqueous solution of NaHCO₃ (10 mL). The aqueous layer was extracted with DCM (3 x 10 mL) and the combined organic layers

were dried over Na₂SO₄ and filtered. Evaporation of the solvent under reduced pressure yielded the crude ketone, which was purified by column chromatography (heptane/EtOAc 98:2 to 60:40).

3.2.4. General procedure 4 (GP4): Formation of silyl enol ethers from ketones

A vial was loaded with the corresponding ketone (1.0 eq.), triethylamine (5.0 eq.), and DCM (0.2 M). The solution was cooled to 0 °C and TMSOTf (3.0 eq.) was added dropwise. The resulting mixture was allowed to warm to room temperature and then stirred for 16 h before stopping the reaction by addition of a saturated aqueous solution of NH₄Cl. The aqueous layer was extracted with DCM (3 x 10 mL). The combined organic phases were dried over MgSO₄. After evaporation of the organic solvent under reduced pressure, the crude material was further purified by column chromatography (heptane/toluene 95:5). All products were obtained at greater than 20:1 Z/E ratio (as judged by NMR analysis), unless otherwise indicated.

3.2.5. General procedure 5 (GP5): Diastereoselective Umpolung cyclization

To a vigorously stirred solution of (PhI)₂O(SbF₆)₂ (**VI**, 0.5 eq.) in dichloromethane (0.1 M) at -15 °C, a solution of the corresponding silyl enol ether (1.0 eq., 0.1 M in DCM) was added dropwise. The resulting solution was stirred for 5 min at -15 °C before saturated aqueous solution of NaHCO₃ was added. The mixture was allowed to warm to room temperature and left stirring for an additional 10 min. The phases were separated and the aqueous phase was extracted once again with CH₂Cl₂. The combined organic phases were washed with brine, dried over MgSO₄, filtered and concentrated in vacuo. The resulting crude

material was purified by flash column chromatography on silica gel (heptane/ethyl acetate, 1:1) to afford the desired products.

The mixture was warmed to room temperature over 30 min and TMSCl (1.3 eq., 1.3 mmol, 330 μ L) was added. The reaction was stirred for 5 h at room temperature. The volatiles were removed under reduced pressure and the residue was dissolved in a minimal amount of CHCl₃. The dissolved crude was loaded on a silica plug, which was rinsed quickly with heptanes (ca. 200 mL). After evaporating the solvent, the product was obtained as a colorless liquid (195 mg, 0.73 mmol, 73%).

A modified reported procedure was used (2.5 mmol scale).²⁴

(4-Methylpent-3-en-1-yl)-magnesium bromide was prepared according to step 1 of GP2 (3.25 mmol). The Grignard solution was subsequently cooled to 0 °C and CuI (95.7 mg, 0.5 mmol, 0.2 eq.) was added in one portion. The resulting suspension was stirred at 0 °C for 5 min before the solution was further cooled to -78 °C. Next, chlorotrimethylsilane (1.5 mL) and triethylamine (1.5 mL) were rapidly added, followed by *N,N,N',N'*-tetramethylethylenediamine (0.49 mL, 3.25 mmol, 1.3 eq.). Finally, 1-phenylprop-2-en-1-one (330 mg, 2.5 mmol, 1.0 eq.) was added dropwise to this mixture at -78 °C and the reaction mixture was allowed to warm to room temperature and subsequently stirred for 16 h.

The solvent was removed in vacuo and the resulting crude material was immediately subjected to column chromatography. The title compound was obtained as a colorless liquid (148 mg, 0.68 mmol, 27%).

4. Experimental Mechanistic Studies

4.1. Detection of oxocarbenium VII and TMS₂O (VIII)

¹³C NMR (101 MHz, CD₂Cl₂)

4.2. Umpolung Cyclization with **1f-d₂**

Preparation of substrate **1f-d₂**:

Compound **1f-d₂** was prepared using a previously slightly modified procedure.²⁶

1-(4-(Trifluoromethyl)phenyl)hept-6-en-1-one (1.0 eq., 0.37 mmol, 95.1 mg) and ethylene glycol (3.0 eq., 1.11 mmol, 62 μ L) were dissolved in benzene (2 mL). *p*-TSA (10 mol%, 0.04 mmol, 7.5 mg) was added to the solution, and the mixture was heated at reflux (oil bath temperature *ca.* 95 °C) using a Dean-Stark apparatus and a condenser. After 16 h, the reaction was allowed to cool to room temperature and a saturated aqueous solution of NaHCO₃ was added (25 mL). The separated aqueous layer was extracted with Et₂O (3 x 10 mL) and the combined organic phases were dried over Na₂SO₄ and filtered. After removing the solvent under reduced pressure, the ketal **S2** was obtained as a colourless liquid (110 mg, >95% yield).

The crude ketal (1.0 eq., 0.36 mmol, 108 mg) was dissolved in a mixture of 1,4-dioxane (3.75 mL) and H₂O (1.25 mL). Lutidine (2.0 eq., 0.71 mmol, 80 μ L), sodium periodate (4.0 eq., 1.44 mmol, 0.5 mg) and a solution of OsO₄ in H₂O (2 mol%, 4 w/w%, 46 μ L) were added in that order and the resulting solution was stirred until full consumption of the starting material was observed by TLC (3 h). The reaction was stopped by addition of H₂O (10 mL) and a saturated aqueous solution of Na₂S₂O₄ (10 mL). CH₂Cl₂ (10 mL) was added, the phases were separated and the aqueous layer was further extracted with CH₂Cl₂ (3 x 10 mL). The combined organic layers were dried over Na₂SO₄, filtered and volatiles were removed under reduced pressure. The crude mixture was purified by column chromatography (heptanes:EtOAc, 100:0 to 50:50 v/v%) to yield the aldehyde **S3** as a yellow liquid (110 mg, >95% yield).

The Wittig salt ($\text{PPh}_3\text{CD}_3\text{I}$, 1.5 eq., 0.525 mmol, 213 mg) was suspended in THF (11 mL) and cooled to 0 °C. A solution of *n*-BuLi (1.5 eq., 0.525 mmol, 33.7 mg, 0.200 mL, 2.5 M in hexane) in THF was added dropwise and the reaction mixture was stirred until the solution became clear. Then the mixture was cooled to -78 °C and a solution of the aldehyde (1.0 eq., 0.35 mmol, 106 mg) in THF (2 mL) was added. The mixture was warmed to room temperature and stirred until no aldehyde was observable by TLC. Thereafter, a saturated aqueous solution of NH_4Cl was added (25 mL). Then the aqueous phase was extracted with more Et_2O (3 x 10 mL), the combined organic layers were dried over Na_2SO_4 , filtered, and the volatiles were removed under reduced pressure. Column chromatography (heptanes:EtOAc, 100:0 to 60:40) gave the compound **S4** as a colorless liquid. The latter was then suspended in acetone (3 mL) and *p*-TsOH (2.0 eq., 0.70 mmol, 133 mg) was added. The mixture was stirred at 25 °C for 16 h. Then, saturated aqueous NaHCO_3 solution (25 mL) was added and the aqueous phase was extracted with EtOAc (3 x 10 mL). The combined organic phases were dried over Na_2SO_4 , filtered, and the volatiles were removed under reduced pressure. The crude material was directly used in the next step without further purification.

A vial was loaded with ketone **S5** (1.0 eq., 0.35 mmol, 65 mg), triethylamine (5.0 eq., 1.71 mmol, 173 mg, 2.35 mL), and DCM (0.2 M). The solution was cooled to 0 °C and TMSOTf (3.0 eq., 1.02 mmol, 232 mg, 0.829 mL) was added dropwise. The resulting mixture was allowed to warm to room temperature and subsequently stirred for 16 h before stopping the reaction by addition of a saturated aqueous solution of NH_4Cl (25 mL). The aqueous was extracted with DCM (2 x 10 mL). The combined organic phases were dried over MgSO_4 and filtered. After evaporation of the organic solvent, the crude material was further purified by column chromatography (heptanes:EtOAc, 100:0 to 95:5) to yield the **1f-d₂** as a yellow liquid (0.16 mmol, 43.0 mg, 48%).

5. DFT calculations

The conformational space of all molecules has been initially searched using meta-dynamics simulations based on tight-binding quantum chemical calculations as implemented in the software package conformer-rotamer ensemble sampling tool CREST.^{27,28} The structures located with CREST have then been subjected to PBE0-D3(BJ)/def2-SVP geometry optimization.^{29–33} The nature of all stationary points (minima and transition states) was verified through the computation of the vibrational frequencies. The thermal corrections to the Gibbs free energies were combined with the single point energies calculated at the PBE0-D3(BJ)/def2-TZVP level of theory to yield Gibbs free energies (" G_{298} ") at 298.15 K. All energies are reported in kcal·mol⁻¹. The energy profiles were constructed using the most stable conformation (the global minimum) of each intermediate and transition state. The density functional theory (DFT) calculations have been performed with the Gaussian 16 program package.³⁴ The polarizable continuum model (PCM) with SMD parameters, including refined iodine parameters (SMD18),³⁵ for dichloromethane,^{36–38} was applied to consider solvent effects for both geometries and energies. Free energies in solution have been corrected to a reference state of 1 mol·l⁻¹ at 298.15 K through the addition of $RT\ln(24.46) = +7.925$ kJ·mol⁻¹ to the gas phase (1 atm) free energies.

5.1. Thermodynamic comparison of I–C and I–O interactions

In this work, we have computationally studied the mechanism for the formation of an oxocarbenium intermediate, which undergoes hydrolysis to form a hydroxylated product. As discussed in the main text, the reaction of the silyl enol ether substrate with the used hypervalent iodine reagent, $I(OPh)_2^{2+}$, is promoted through an initial I–C bond formation. It was previously observed by the Szpilman group that an I–O interaction can be preferential with the use of $PhI(OH)(OTs)$ as a hypervalent iodine reagent.³⁹ We have therefore computed the relative thermodynamic stability of the possible I–O and I–C interactions considering all four combinations of the silyl enol ether and the iodine reagent studied in this work and the silyl enol ether and iodine reagent reported by Szpilman and co-workers (Figure SI-1). In the four presented systems, the intermediates featuring an I–C bond are more stable than the alternative structure with an I–O bond. Specifically, **SI-A** is 20.4 kcal/mol more stable than **SI-A'**, and **SI-B** is 25.1 kcal/mol more stable than **SI-B'** (Figure SI-1-A). Similarly, in the neutral system, **SI-C** is 8.7 kcal/mol more stable than **SI-C'**, and **SI-D** is 5.7 kcal/mol more stable than **SI-D'** (Figure SI-1-B). The increased stability of the intermediates presenting an I–C bond is highly accentuated by the electron-deficient nature of the cationic iodine reagent used in this work.

Figure SI-1 – Thermodynamic comparison of key intermediates presenting either C-I or C-O bond. A) considering the hypervalent iodine reagent studied in this work; B) Considering the neutral hypervalent iodine reagent studied by Szpilman and co-workers. Relative Gibbs free energies are presented in kcal/mol.

5.2. The influence of the counterion on the reaction mechanism

In some cases, the inclusion of counterions in quantum chemical calculations of charged species can be crucial. However, for the studied mechanism, we do not expect any dramatic effect from the counterion, as it cannot form strong intermolecular interactions with either the intermediates or the transition states due to its chemical nature (SBF_6^-). Nevertheless, we have assessed the influence of the counterion by repeating the calculations for the **C**→**D** step, this time including SBF_6^- . Figure SI-2 shows the resulting pathway comparison: the black line represents the **C**→**D** step without the counterion, while the red line shows the pathway with it included. Naturally, various possible relative positions of the ions were considered through a full conformational search. Although we observe some quantitative differences in the characteristics of the Gibbs free energy reaction profile, the overall mechanism remains unchanged. The transformation proceeds as a concerted process that is highly favorable both kinetically and thermodynamically, regardless of whether the counterion is included.

Figure SI-2 – Computed energy profiles (relative Gibbs free energies in kcal/mol) for step **C**→**D** without considering counterion (shown in black) and involving the counterion (shown in red color) in comparison. The intermediate **C** is taken as the reference (0.0 kcal/mol).

Cartesian coordinates of the most stable (ΔG_{298}) conformations, computed at the PBE0-D3(BJ),SMD(DCM)//def2-TZVP//PBE0-D3(BJ)/def2-SVP level of theory. For the structures **SI-A**, **SI-A'**, **SI-B**, **SI-B'**, **SI-C**, **SI-C'**, **SI-D** and **SI-D'** the SMD model was also applied during geometry optimization.
