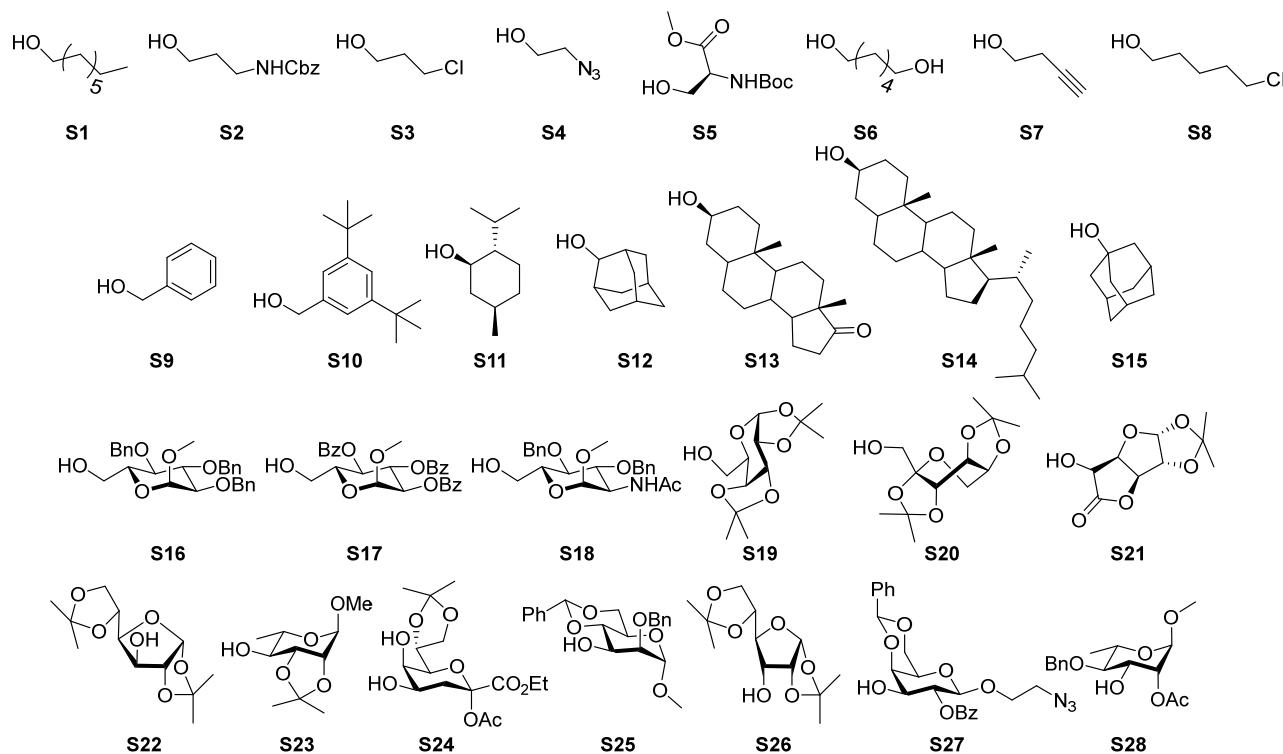

**Figure S1.** Previous work on Kdo glycosidation by the ionic activation.

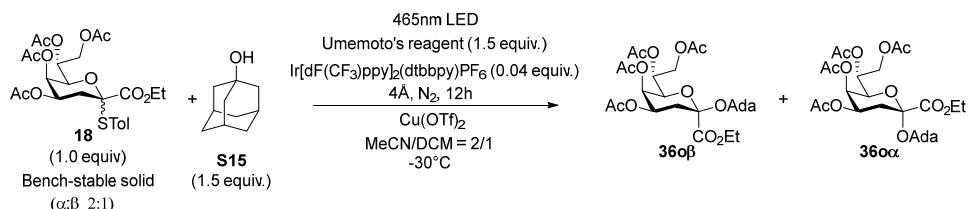

As shown in Figure S1, various strategies (**6-25**) have been developed for the efficient synthesis of  $\alpha$ -Kdo glycosides, including using bulky protecting group to limit the  $\beta$ -face attack of receptors with strong steric hindrance,<sup>[1]</sup> adding exogenous nucleophile such as DMF<sup>[2]</sup> or  $(p\text{-Tol})_2\text{SO}$ <sup>[3]</sup> to stabilize oxacarbenium ion, and utilizing solvent and ion effect.<sup>[4]</sup> Moreover, some indirect methods have been published to better achieve complete  $\alpha$ -stereocontrol and less byproduct, such as introducing an auxiliary group (-I,<sup>[5a]</sup> -SPh<sup>[5b]</sup> and -STol<sup>[5c, 5d]</sup>) at C3 position and the conversion from Ko<sup>[6]</sup> or 2,3-ene.<sup>[7]</sup> These indirect ways need more additional steps to construct the special donors and the target Kdo glycosides.

Nevertheless, the researches on the stereoselective synthesis of  $\beta$ -Kdo glycosides (**26-30**) are relatively limited. Kdo 2,3-ene, which was initially applied to synthesizing  $\alpha$ -Kdo glycosides, was otherwise used to construct the  $\beta$ -Kdo glycosidic linkages with AIBN as activator by Mong's group in 2014.<sup>[8]</sup> In 2016, Gauthier and co-workers<sup>[9]</sup> introduced the 4'-methoxyphenacyl group at C1 position as an auxiliary group to generate  $\beta$ -Kdo O-glycosides through an  $\alpha$ -spiroPhen intermediate. Yang's group<sup>[10]</sup> used a Kdo thioglycoside donor with the quinolinecarbonyl group at the C5 position as an auxiliary group to generate  $\beta$ -Kdo glycoside for 1° acceptors through the hydrogen-bond mediation. In 2020, with the effect of side chain configuration and conformation, Crich's group<sup>[11]</sup> disclosed a novel methodology for the synthesis of  $\beta$ -Kdo O-glycosides. Recently, Saha et al.<sup>[12]</sup> used  $\alpha$ -

acyloxyhydroxamate as the glycosyl donor to generate  $\beta$ -Kdo glycosides in moderate yields by forming an  $\alpha$ -lactam-like species which could block the  $\alpha$ -face of the anomeric center.

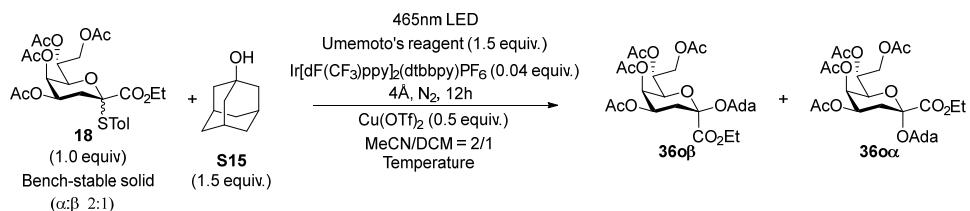

**Figure S2.** The chemical structures of various glycosyl acceptors **S1-S28**. **S1-S10** are non-carbohydrate alcohols with primary hydroxyl groups, while **S11-S14** are non-carbohydrate alcohols with secondary hydroxyl groups. **S15** is tertiary alcohol. **S16-S20** are sugar acceptors with primary hydroxyl groups, and **S21-S28** are sugar acceptors with secondary hydroxyl groups.

**Figure S5.** Calculated absorption spectra at the TD-B3LYP-D3(BJ)/6-311+G(d, p)/SMD/(MeCN/DCM = 1:1) level of theory. UV-Vis peak half-width at half height was set at 0.3 eV. (a) for  $\cdot\text{CF}_3$ ; (b) for  $\text{R}_1\text{S}^+$ ; (c) for  $\mathbf{18}^+$ ; (d) for  $\mathbf{32}$ ; (e) for  $\mathbf{33}$ ; (f) for  $\mathbf{48}$ ; (g) for Kdo glycosyl radical.

**Figure S6.** (a) The input structure of  $\mathbf{32}^+$ ; (b) The optimized structure of  $\mathbf{32}^+$  obtained at the level of B3LYP-D3(BJ)/6-311+G(d, p)/SMD/(MeCN/DCM = 1:1).

In comparison with the input structure of  $\mathbf{32}^+$  cation, the optimized structure reveals that  $\text{CF}_3\text{STol}$  (**48**) has been already detached, suggesting the expulsion of **48** from the  $\mathbf{32}^+$  cation to yield the oxacarbenium ion **33** is a barrier-free process. Consequently, once this cation is formed, a rapid detachment of **48** can be anticipated.

---

**Note:**

In Figure S3f, the transient absorption spectra resulting from the homolytic cleavage of **31** upon individual excitation and that arising from the quenching of  ${}^3\text{Ir}^{\text{III}*}$  by **31** both exhibit a characteristic absorption band around 450 nm. If the quenching of  ${}^3\text{Ir}^{\text{III}*}$  by **31** were solely governed by the Dexter energy transfer pathway, its the spectral signature would necessarily coincide precisely with the transient absorption spectrum observed from the homolytic cleavage of **31** excited independently. However, upon meticulous comparison of the transient absorption spectra under these two conditions, subtle differences emerge near 400 nm and within the 500-600 nm region: the spectrum resulting from the reaction of  ${}^3\text{Ir}^{\text{III}*} + \mathbf{31}$  displays negative signals near 400 nm and slightly stronger absorption signals in the 500-600 nm range, compared to the system where **31** is excited alone. This observation suggests the presence of additional transient species beyond those generated solely by homolytic cleavage in the  ${}^3\text{Ir}^{\text{III}*} + \mathbf{31}$  system. This extra transient species indicates that the  ${}^3\text{Ir}^{\text{III}*} + \mathbf{31}$  reaction encompasses quenching pathways other than energy transfer. Upon observing novel spectral features, including negative signals near 400 nm and positive absorption within the 500-600 nm range, which mirror signals documented in literature for oxidized Ir photocatalyst ( $\text{Ir}^{\text{IV}}$ )<sup>[18]</sup>, and considering the thermodynamic favorability of **31** quenching  ${}^3\text{Ir}^{\text{III}*}$  through electron transfer, as supported by redox potential calculations (Table S6, Entry 1), we hypothesize that, in addition to the primary Dexter energy transfer pathway, an electron transfer quenching mechanism may also contribute to the quenching reaction between  ${}^3\text{Ir}^{\text{III}*}$  and **31**.

For Figure S3g, given that the generation of species **18<sup>+</sup>** and its decay occur concurrently at the initial time, to eliminate the interference from the process of species **18<sup>+</sup>** generation and ensure a more accurate description of its decay kinetics, we chose to analyze its decay behavior starting from 15  $\mu\text{s}$ . We found that its decay can be well described by a second-order reaction behavior, in contrast to the mono-exponential decay.

## 2 Materials and instruments

**General experiments and characterizations.** All reactions were carried out under nitrogen atmosphere unless otherwise stated. Solvents used were analytical grade. Chemical reactions were monitored by analytical thin-layer chromatography (TLC) on silica gel F254 glass plates and revealed by UV light (254 nm) or heating after dipping in EtOH-H<sub>2</sub>SO<sub>4</sub> (7%). Flash column chromatography was performed on silica gel (200-300 mesh). High-resolution mass spectra (HRMS) were obtained in the ESI mode (Bruker micrOTOF-QII mass spectrometer (ESI)). Optical rotation was determined in chloroform or methanol by an automatic polarimeter. NMR spectra were recorded using CDCl<sub>3</sub> as solvents. Chemical shifts ( $\delta$ ) were reported in units per million (ppm) and coupling constants (J) in Hz. <sup>1</sup>H NMR spectra, <sup>13</sup>C NMR spectra and the selective proton decoupled NMR spectra were recorded on JNM-ECZR spectrometer (400 and 600 MHz) or Bruker Avance III spectrometer (500 MHz). EPR spectra were collected on a Bruker E500 spectrometer.

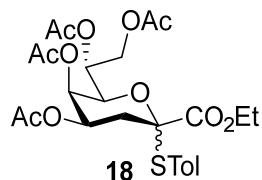

**Laser flash photolysis.** Nanosecond time-resolved transient absorption spectra were measured using a flash photolysis setup Edinburgh LP980 spectrometer (Edinburgh Instruments Ltd.). In this work, the sample was excited by a 430 nm or 355 nm laser pulse (1 Hz, 20 mJ/pulse/cm<sup>2</sup>, fwhm  $\approx$  7 ns). A Surelite II-10 Q-Switched Nd:YAG laser (Continuum) provides third harmonic laser pulses at 355 nm with a repetition rate of 10 Hz and maximum output of 1.5 W. The laser output was directed to a Horizon I Mid-band Optical Parametric Oscillator (OPO) (Continuum) to produce 430 nm pump pulse. The pump pulse of 355 nm is generated by a commercial Nd:YAG laser (Lab 170, Spectral Physics Inc.) Each measurement was performed in a quartz cuvette with 1 cm path length at room temperature. The analyzing light was from a 150 W pulsed xenon lamp. A monochromator equipped with a photomultiplier for collecting the spectral range from 300 to 700 nm was used to analyze transient absorption spectra. The signals from the photomultiplier were displayed and recorded as a function of time on a 100 MHz (1.25 Gs/s sampling rate) oscilloscope (Tektronix, TDS 3012C), and the data were transferred to a personal computer. The fitting quality was judged by weighted residuals and reduced  $\chi^2$  value.

**Steady-state Spectral Measurement.** The UV-vis absorption spectra were measured using a UV-vis spectrometer (U-3010, Hitachi). Each measurement was collected from 300 to 700 at a scan speed of 600 nm/min. The spectrum of a blank sample containing the pure solvent was used as the background, which was subtracted from the averaged spectra. Emission spectra were measured on a fluorescence spectrometer (F4600, Hitachi). Quartz cuvettes of 1  $\times$  1 cm were used for all absorption and emission spectral measurements.

## 4 X-ray Crystallography

Appropriate crystals for X-ray diffraction study were obtained by slow evaporation of petroleum ether/dichloromethane (4:1, v/v) solutions of compounds **36pa** and **36ta**, respectively.

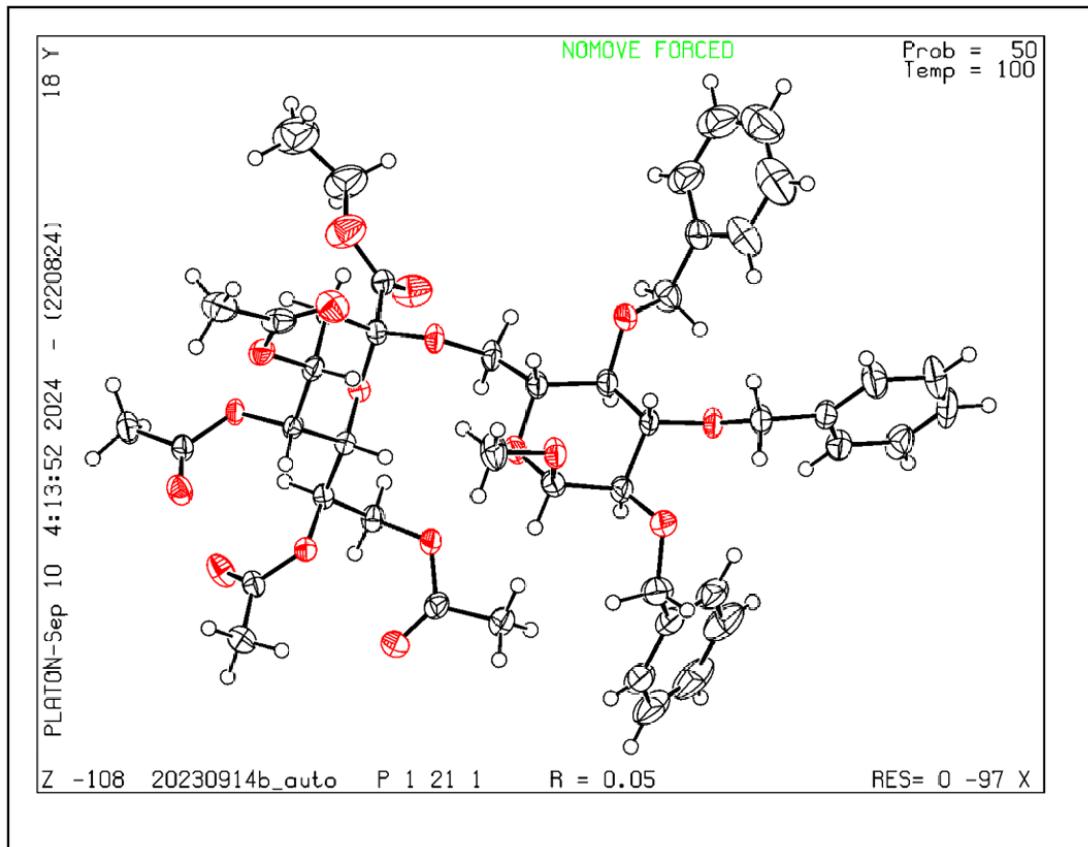

Single crystal X-ray diffraction data of **36pa** were collected on a Rigaku Super Nova, Dual, Mo at zero, AtlasS2 diffractometer. The crystal was kept at 100 K during data collection

Single crystal X-ray diffraction data of **36ta** were collected on a Rigaku Super Nova, Dual, Mo at zero, AtlasS2 diffractometer. The crystal was kept at 100 K during data collection.

Using Olex2, the structure was solved with the ShelXT structure solution program using Direct Methods and refined with the ShelXL refinement package using Least Squares minimization. The disordered solvent molecules were removed with the SQUEEZE routine in PLATONS and the solvent-free model was employed for the final refinement. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were positioned by geometric idealization. Details of the crystal data and a summary of the intensity data collection parameters for **36pa** and **36ta**, are listed in **Section 5** and **6**. Crystallographic data were deposited at the Cambridge Crystallographic Data Center (CCDC 2382908 for **36pa**, 2382909 for **36ta**). The data can be obtained free of charge from The Cambridge Crystallographic Data Centre via [www.ccdc.cam.ac.uk/structures](http://www.ccdc.cam.ac.uk/structures).

## 5 Computational methods and data

**Computational methods.** All calculations were carried out utilizing the Gaussian 16 program package.<sup>[26]</sup> All geometries of reagents, intermediates, transition states, and products were optimized by employing the B3LYP-D3(BJ) functional method<sup>[27-29]</sup>, with the 6-311+g(d,p) basis set<sup>[30-34]</sup> for all elements. The solvent effect of the 1:1 mixture of dichloromethane (DCM) and acetonitrile (MeCN) was considered by the SMD model<sup>[35]</sup> (Eps=22.309, EpsInf=1.91761, HBondAcidity=0.085, HBondBasicity=0.185, SurfaceTensionAtInterface=40.18, CarbonAromaticity=0.000, ElectronegativeHalogenicity=0.333). The vibrational frequencies of all optimized stationary point structures were calculated at the same level of theory to obtain zero-point energies and Gibbs free energies. The optimized stationary point structures were subsequently characterized by frequency analyses at the same level of theory, from which zero-point energies and relative free-energies were obtained, in addition to conforming the stationary points to be either local minima (no imaginary frequencies) or transition states (one imaginary frequency). Moreover, intrinsic reaction coordinate (IRC)<sup>[36]</sup> calculations were carried out to confirm that the optimized transition states connect to their respective reactants and products. The vertical electronic excitations were calculated using time-dependent (TD)-B3LYP-D3(BJ) method based on the ground-state geometry optimized at the same level. Using SHERMO program to calculate the solutional free energy for all species (scfZPE=0.9887).<sup>[21]</sup>
