1. General information

Unless otherwise noted, materials were purchased from commercial suppliers and used without further purification. Flash column chromatography was performed using 200-300 mesh silica gel. ^1H NMR spectra were recorded on 300 or 400 MHz spectrophotometers. Chemical shifts are reported in ppm relative to tetramethylsilane (TMS) with the solvent resonance employed as the internal standard (CDCl_3 : $\delta = 7.26$ ppm). ^{13}C NMR was recorded at 75 MHz or 101 MHz: chemical shifts are reported in ppm from tetramethylsilane (TMS) with the solvent resonance as the internal standard (CDCl_3 : $\delta = 77.00$ ppm). Electron impact (EI) mass spectra were recorded on AMD 402 mass spectrometer (70 eV). High resolution mass spectra (HR-MS) were recorded on Agilent 6210. The data were given as mass units per charge (m/z). Gas chromatography analysis was performed on an Agilent HP-5890 instrument with an FID detector and HP-5 capillary column (polydimethylsiloxane with 5% phenyl groups, 30 m, 0.32 mm i.d., 0.25 μm film thickness) using argon as carrier gas. Because of the high toxicity of carbon monoxide, all the reactions should be performed in an autoclave. The laboratory should be well-equipped with a CO detector and alarm system.

2. Preparation of substrates

2.1 Preparation of NHPI Ester 3

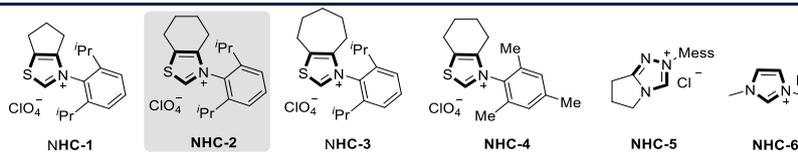

A Schlenk flask equipped with a stir bar and a septum was flushed with argon and charged with dry THF (0.5 M). The carboxylic acid (1.0 equiv.), N,N'-dicyclohexylcarbodiimide (DIC, 1.2 equiv.), 4-dimethylaminopyridine (DMAP, 0.1 equiv.) were added. After stirring for one minute, N-hydroxyphthalimide (NHPI, 1.1 equiv.) was added and the reaction mixture was stirred for 24 h at room temperature. The precipitating dicyclohexyl urea was filtered off and the solution was concentrated by evaporation of the solvent. Flash column chromatography afforded the desired product. N-(Cyclohexylcarbonyloxy)phthalimide (3).^[1]

4. Characterization and procedure of 1,4-dione products

4.1 General diacylation procedure for the synthesis of 1,4-diones 4

A 4 mL screw-cap vial was charged with NHPI ester **3** (1.0 equiv), NHC-2 (10 mol%), ZnCl₂ (50 mol%), Cs₂CO₃ (15 mol%) and an oven-dried stirring bar. The vial was closed with a Teflon septum and cap and connected to the atmosphere via a needle. After replacing the nitrogen in the vial three times, alkenes **2** (4.0 equiv) was added. Then, aryl aldehydes **1** (2.0 equiv) and DMSO was added using injector. The vial was then moved to a cannula and transferred into a 300 mL photoautoclave (manufactured by Parr Instrument Company®), under a nitrogen atmosphere. At room temperature, the autoclave was washed with CO three times and charged with 50 bar of CO. The autoclave was placed on a heating plate equipped with a magnetic stirrer and an aluminum block. The reaction mixture was allowed to react at 80 °C for 30 hours. After the reaction was complete, the pressure of the autoclave was carefully released, and the residual CO was washed away with nitrogen. The solvent was wash by NH₄Cl (aq.) and ethyl acetate, then removed under vacuum, and the product was purified by column chromatography on silica gel using petroleum ether and ethyl acetate (50:1) to afford the corresponding product **4**.

5. Mechanistic investigation

5.1 Control Experiments and Mechanistic Studies

Scheme 1 Control Experiments and Mechanistic Studies

Based on the standard conditions, a series of control experiments were conducted (Scheme 1, eqs a–c). First, the addition of 2,2,6,6-tetramethylpiperidin-1-oxyl (TEMPO) as a radical scavenger completely suppressed the formation of product **4a** under standard conditions (**Figure 1** and **Scheme 1a**). Instead, the benzoin condensation (**4a''**) and aldehyde alkylation (**4a'''**), cyclohexyl–TEMPO adduct **5aa** and PhthH was detected by GC–MS, supporting the involvement of alkyl radical intermediates.^[2] Next, a control experiment without alkenes to explore main by-product (**Figure 2** and **Scheme 1b**), with the benzoin condensation (**4a''**) and aldehyde alkylation (**4a'''**) detected by GC–MS analysis.^[3] In addition, treatment of the reaction with 3-phenylpropanoic NHPI ester, employed to probe the involvement of the Breslow intermediate, led to the formation of adduct **5ac** (**Figure 3** and **Scheme 1c**).^[4] Collectively, these results support a radical-based single-electron-transfer (SET) pathway.
