#### 1. General Considerations

All manipulations, unless otherwise stated, were performed under an argon atmosphere using standard Schlenk line and glove-box techniques. Hydrogen gas was supplied by BOC Gases. Glassware was oven-dried at 130 °C overnight and flamed under vacuum prior to use. THF and Toluene were dried using a Grubbs-type solvent purification system (Innovative Technologies SPS) equipped with a degasser. Polycaprolactone (M<sub>n</sub> = 80,000 Da), 2-methyltetrahydrofuran (anhydrous) and ethanol (anhydrous) were purchased from Sigma-Aldrich. Afterwards, the solvents were degassed by flushing them with argon through an argon lance equipped with a frit. The solvents were dried and stored in glass Schlenk flask over molecular sieves 3 Å or 4 Å. Ruthenium complex 1 was purchased from TCI and used as received. Manganese complexes 2 and 3 were synthesized following the procedure described in the literature.¹ Complex 4 was bought from Thermo Scientific and complexes 5, 6, 7, and 8 were donated by Johnson Matthey.

KOtBu, KOH, and NaOtBu were purchased from Sigma-Aldrich, and TCI and stored at 80 °C and dried in oven before use. NMR solvents were purchased from Sigma-Aldrich and used as received.

NMR spectra were recorded on a Bruker AVII 500 MHz and Bruker Neo 400 MHz NMR spectrometer at 298 K unless otherwise specified. Residual proton solvent was used as reference for  $^1$ H spectra in deuterated solvent samples. All chemical shifts ( $\delta$ ) are quoted in ppm and coupling constants (J) in Hz. GC-MS (Gas Chromatography-Mass Spectrometry) data was collected using Agilent 8860 GC system coupled to an Agilent 5977B EI instrument. Helium was used as carrier gas with a column flow of 1.87 mL/min. SH-RTx-1 (100% dimethyl polysiloxane, 30 m) was used as a column. Ion source temperature of 200 °C, and injection temperature of 330 °C were used. The oven temperature range was from 50 °C to 250 °C (start with 50 °C, hold for 4.2 minutes, followed by a temperature ramp of 10°C/minute for 15 minutes and stay at 250 °C until 39 minutes).

#### 2. Procedure for hydrogenolysis of Polycaprolactone

#### General method for the hydrogenation of Polycaprolactone:

Polycaprolactone (114 mg, 1 mmol relative to the monomer, 1eq.) and KOtBu {11.2 mg, 0.1 mmol, 10 mol%, 0.1 mL (1M solution in THF)} were weighed in an 8 mL glass vial with a stirrer and sealed with a crimp cap using a crimper. The vial was cycled with argon (3 times) with needle at the top and syringe connected to the Schlenk line, and 2-MeTHF (2 mL) and ethanol (0.25 mL) were added by syringe. A 2 mM stock solution of the catalyst was prepared by dissolving 0.01 mmol of precatalyst in 5 mL of 2 Me-THF in another vial under argon atmosphere. 0.25 mL (0.05 mol% of precatalyst) of the precatalytic solution was transferred to the reaction vial by syringe. The vial was placed into a 150 mL autoclave with metal beads to ensure thermal conductivity. The autoclave was purged with argon, sealed,

purged with  $H_2$ , and pressurised with  $H_2$  at 60 bar. It was then placed in a preheated oil bath at 80 °C and stirred for 20 h. After the completion of reaction, the autoclave was cooled to room temperature and  $H_2$  gas was carefully vented to atmosphere. 1 mmol of internal standard (mesitylene) was added into the reaction mixture and the yield of the product was estimated by GC-MS quantitative analysis. The method for product isolation has been described in Section 3.

#### Method for the hydrogenation of Polycaprolactone under solvent-minimised conditions:

Polycaprolactone (114mg, 1mmol, 1eq.) and KOtBu  $\{5.6 \text{ mg}, 0.05 \text{ mmol}, 5 \text{ mol}\%, 0.05 \text{ mL}\}$  were weighed in an 8mL glass vial with a stirrer and sealed with a crimp cap using a crimper. The vial was cycled with argon (3 times) with needle at the top and syringe connected to the Schlenk line, and 0.25 mL of Ethanol was added by syringe. A 2 or 5 mM stock solution of the catalyst was prepared by dissolving 0.01 mmol of precatalyst in 5 or 2 mL of 2 Me-THF (for precatalyst 8) or Ethanol (for precatalyst 7) in another vial under argon atmosphere. The required amount of precatalytic solution was transferred to the reaction vial by syringe. The vial was placed into a 150 mL autoclave with metal beads to ensure thermal conductivity. The autoclave was purged with argon, closed, purged with H<sub>2</sub> and pressurised with H<sub>2</sub> at 60 bar. It was then placed in a preheated oil bath at 80 °C and stirred for 20 h. After the completion of reaction, the autoclave was cooled to room temperature and H<sub>2</sub> gas was carefully vented to atmosphere. 1 mmol of internal standard (Mesitylene) was added into the reaction mixture and the yield of the product was estimated by GC-MS quantitative analysis.

### 3. Method for the isolation of 1,6-hexanediol

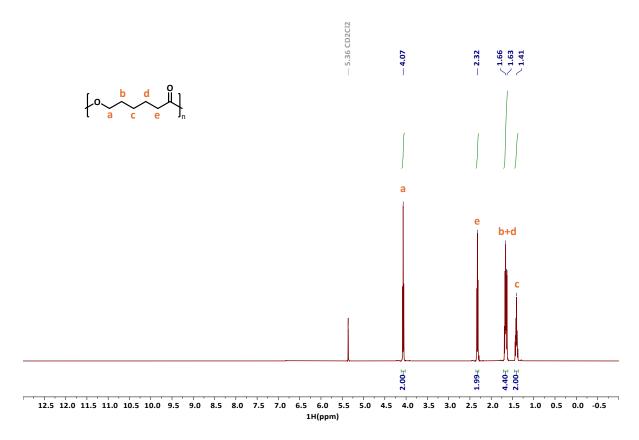

The reaction mixture (Table 2, entry 8) was cooled to room temperature. Ethanol (2-5 mL) was then added to the residue, followed by vacuum filtration to remove any starting material left as the desired product is soluble in ethanol whereas the starting material (polycaprolactone) is insoluble in ethanol. The solution containing the product was concentrated using a rotary evaporator to remove the ethanol. It was then extracted with toluene/water mixture to remove the catalyst. 1,6-hexanediol is soluble in water and the catalyst separated by dissolving in Toluene. The aqueous solution was concentrated using the rotary evaporator. Finally, the pure 1,6-hexanediol was dried under vacuum on a Schlenk line for at least 2 hours, yielding the final product in 91% yield.

#### 4. Characterisation of commercial polycaprolactone

275.1900

\* We speculate that the peak at 22.4 min could be due to the dimer formed during the GC-MS analysis due to high temperatures.

# 6. Characterisation of commercial ε-caprolactone

<sup>1</sup>H NMR (500 MHz, CD<sub>3</sub>OD): δH 4.31 (t, -O-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CO-), 2.69 (t, -O-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CO-), 1.86-1.81 (m, -O-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CO-).

 $^{13}\text{C}^{1}\text{H} \} \text{ NMR } (126 \text{ MHz}, \text{CD}_{3}\text{OD}) : \delta \text{C } 177.85 (-\text{O-CH}_{2}\text{-CH}_{2}\text{-CH}_{2}\text{-CH}_{2}\text{-CH}_{2}\text{-CO-}), 69.14 (-\text{O-CH}_{2}\text{-CH}$

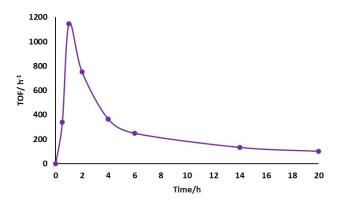

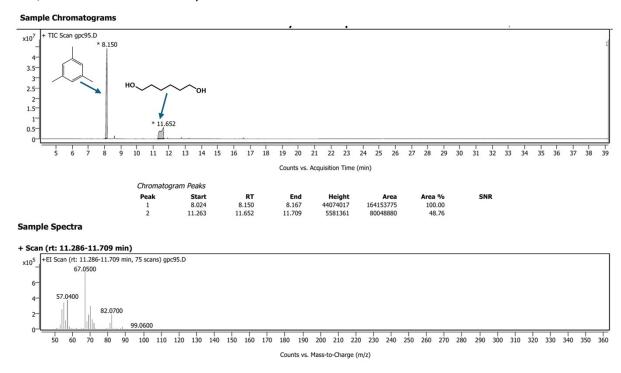

Figure S53. Turnover frequency (TOF) data for the hydrogenation reaction at different time intervals.

## 11. Reaction with ε-caprolactone

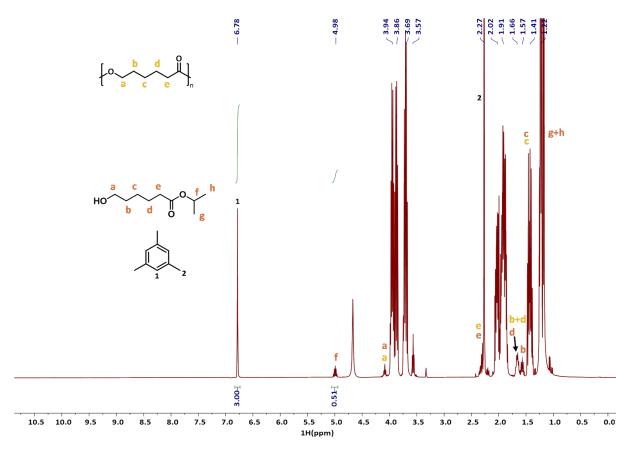

The hydrogenation reaction with  $\epsilon$ -caprolactone as substrate was conducted instead of PCL using the same reaction conditions as discussed in Table S1, entry 17, and it resulted in full transformation to 1,6-hexanediol confirmed by the GC-MS.

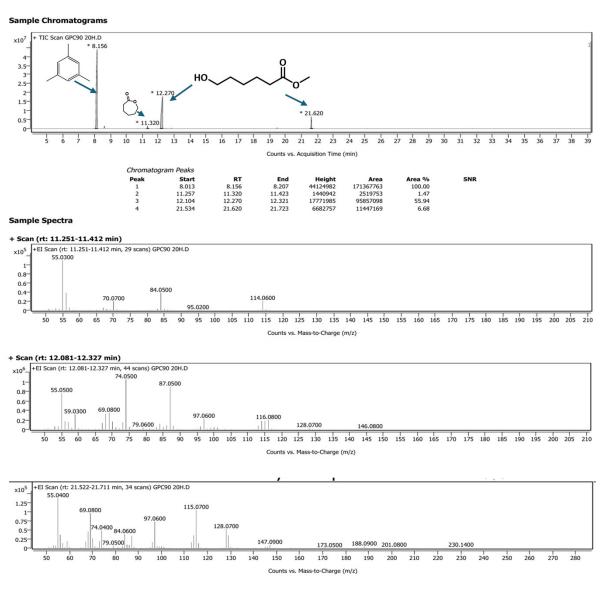

**Figure S54.** GC-MS data of the reaction mixture resulting from the reaction with  $\epsilon$ -caprolactone.

# 12. Role of alcohols in transesterification reactions

The transesterification reactions for different alcohols using the same reaction conditions for 20 h, as described in Fig. 4a in the manuscript were performed. Reaction with methanol resulted in 76% yield of methyl 6-hydroxyhexanoate, and isopropanol resulted in 52% yield of isopropyl 6-hydroxyhexanoate. These suggest that transesterification process can work with multiple alcohols in similar ways.

**Figure S55.** <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD) spectrum of the reaction mixture resulting from the transesterification reaction done by using **isopropanol** as alcohol. Mesitylene is used as an internal standard.

**Figure S56.** GC-MS data of the reaction mixture resulting from the transesterification reaction done by using **methanol** as alcohol. Mesitylene is used as an internal standard.

## 13. Role of temperature in transesterification and hydrogenation reactions

Conducting the transesterification reaction at 60 °C resulted in a 74% yield of E6-HH and a 3% yield of  $\epsilon$ -CPL after 20 h (Figure S56). In contrast, hydrogenation of PCL under identical conditions as entry 17, Table S1(at 60 °C) produced 1,6-hexanediol selectively with 94% yield. Similarly, performing the transesterification reaction at 80 °C for 20 h afforded a 63% yield of E6-HH and a 0.5% yield of  $\epsilon$ -CPL (Figure 4a), while the corresponding hydrogenation yielded >99% 1,6-hexanediol (entry 17, Table S1). These observations indicate that temperature plays a crucial role in the overall process: transesterification proceeds more efficiently at 60 °C, whereas hydrogenation is favoured at 80 °C.

### **Sample Chromatograms**

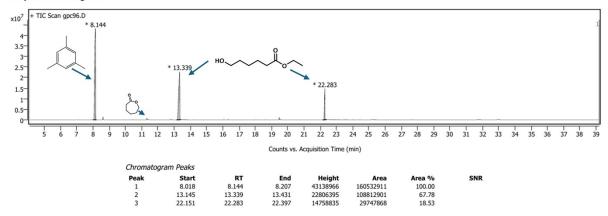

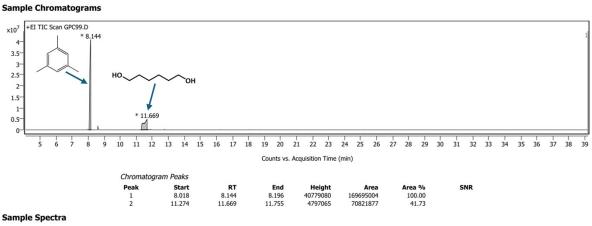

Figure S57. GC-MS data of the reaction mixture resulting from the transesterification reaction conducted at 60 °C. Mesitylene is used as an internal standard.

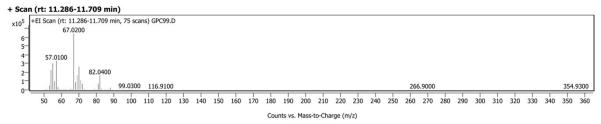

Figure S57a. GC-MS data of the reaction mixture resulting from the hydrogenation reaction conducted at 60 °C. Mesitylene is used as an internal standard.

## 14. Catalyst stability

To evaluate the catalyst stability, the reaction was first conducted for 72 h under the conditions described in entry 6, Table S2. Upon completion, 1 mmol of PCL was added to the reaction mixture, followed by recharging with H<sub>2</sub> gas, and the reaction was continued for an additional 72 h. However, no improvement in the product yield was observed, as confirmed by the NMR spectrum. The process predominantly resulted in depolymerization of the polymer into oligomers or E6-HH through a basemediated transesterification pathway, indicating that the catalyst becomes deactivated after the first cycle.

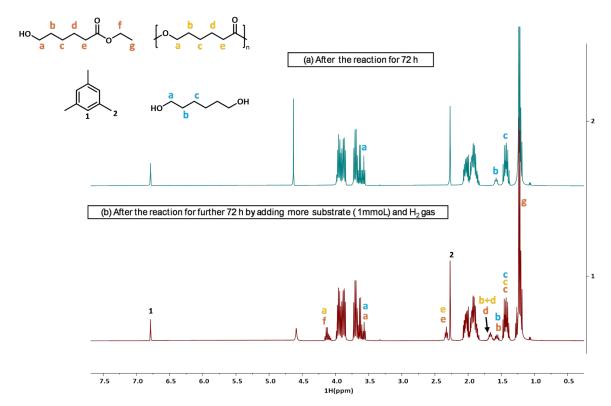

Figure S58.  $^{1}$ H NMR (400 MHz, CD<sub>3</sub>OD) spectrum of the reaction mixture resulting from the reaction corresponding to Table S2; Entry 6. Mesitylene is used as an internal standard.

### **Sample Chromatograms**

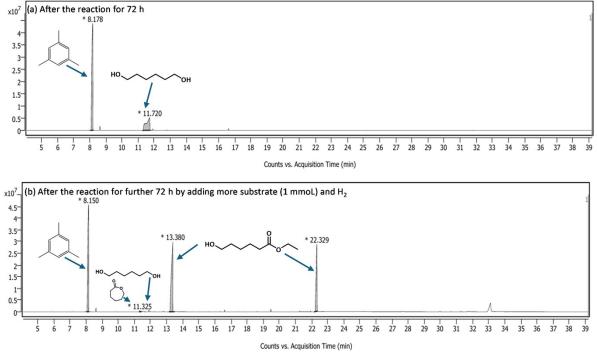

Figure S59. GC-MS data of the reaction mixture resulting from the reaction corresponding to Table S2; Entry 6. Mesitylene is used as an internal standard.

## 15. DFT Studies

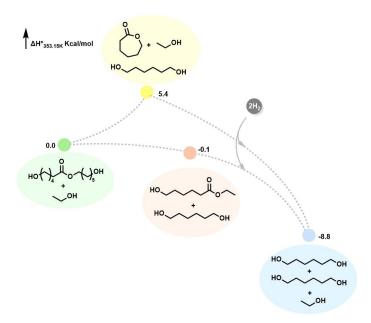

The computational study was carried out using a two-step approach. Initially, geometry optimizations and frequency calculations were performed using the functional B3LYP³ and the 6-21G basis set⁴ to

obtain reliable starting structures. The optimized geometries and frequencies were then re-optimized at the higher B3LYP/6-311G+(d,p)<sup>5</sup> level of theory. Frequency calculations at this level of theory confirmed stationary points and transition states and were used to compute thermodynamic properties at 353.15 K, tetrahydrofuran (THF) as the reaction medium (using PCM as solvent model)<sup>6</sup> and 59.2 atm to match the experimental conditions. Gibbs Free Energies, unless otherwise stated, were computed by adding the Free Energy correction terms from the frequency calculations to the single point energies at the B3LYP/6-311G+(d,p) level of theory in solution (THF).

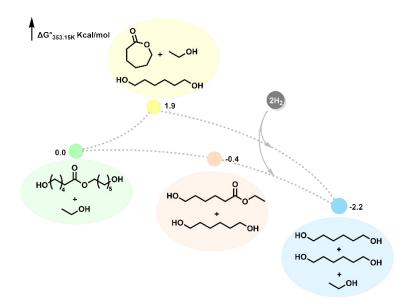

Gibbs free energies were computed by adding the free energy correction term from the frequency calculation to the single point energy in dioxane, according to

$$\mathbf{G}^{\text{B3LYP/6-311G*}(d,p)}_{\text{(THF,353.15K)}} = \mathbf{E}^{\text{B3LYP/6-311G*}(d,p)}_{\text{THF}} + \mathbf{corr}^{\text{B3LYP/6-311G*}(d,p)}_{\text{freq(THF, 59.2 atm, 353.15K)}}$$

Optimizations, frequency calculations and single point energies were done using the Gaussian 16 software suite in the C.01 revision.

**Figure S60.** Enthalpy surface for the depolymerisation of caprolactone dimer to form 1,6-HD. Enthalpies were calculated at 353.15 K, 60 bar and at 1 M concentration of solutes in Kcal/mol.

**Figure S61.** Energy surface for the depolymerisation of caprolactone dimer to form 1,6-HD. Free energies were calculated at 353.15 K, 60 bar and at 1 M concentration of solutes in Kcal/mol.
