

## Experimental Section

*Electrolyte Synthesis:*  $\text{PbSnF}_4$  was synthesized by the following steps: The following reagents were the starting compounds for synthesis: high-purity  $\text{Pb}(\text{NO}_3)_2$  (99.99%, Aladdin); analytically pure  $\text{NH}_4\text{F}$  (99.99%, Aladdin),  $\text{SnF}_2$  (99.99%, Aladdin),  $\text{LiF}$  (99.99%, Aladdin). Firstly, a solution of  $\text{Pb}(\text{NO}_3)_2$  in distilled water was gradually added a threefold excess of a  $\text{NH}_4\text{F}$  solution, the product is obtained through precipitation. Afterward, washing the resulting precipitate several times with distilled water, then dried at 353 K for about 5 h and calcined the  $\gamma\text{-PbF}_2$  at 753-773 K with a heating rate of  $5^\circ\text{C min}^{-1}$ . “As a result,  $\beta\text{-PbF}_2$  was obtained as a precursor. Subsequently,  $\text{PbF}_2$  and  $\text{LiF}$  were thoroughly ground, mixed in a 1:3 molar ratio, and pressed into pellets. The resulting pressed mixtures were heated to 873 K with a heating rate of  $5^\circ\text{C min}^{-1}$  to obtain the final sintered  $\text{PbSnF}_4$  in quartz tubes in a high-purity argon atmosphere and held at this temperature for 5 h with subsequent cooling to room temperature with switched-off furnace. In the third stage, the obtained solid solutions were fused with equimolar amounts of  $\text{SnF}_2$  in crucibles in an argon atmosphere, held at 773 K with a heating rate of  $5^\circ\text{C min}^{-1}$  for 20 min and cooled to room temperature with switched-off furnace. After all the steps, the obtained were nonstoichiometric  $\text{PbSnF}_4@\text{LiF}$  phases. At last, stoichiometric amounts of the materials were mixed in the agate mortar, and then milled using WC balls (5 mm diameter) and WC jars (45 ml) on a planetary mill; the milling was conducted at 500 rpm for 8 h in Ar atmosphere, and the ball-to-powder ratio was 20:1. It was important that all steps should be completed under argon protection.

*Composite Electrode Material Preparation:* because of the reason that  $\text{CuF}_2$  has a poor  $\text{F}^-$  ionic conductivity and electron conductivity, engineering of an additional ionic and electronic were required in order to prepared the composite cathode of  $\text{CuF}_2$ - $\text{PbSnF}_4@ \text{LiF}$ -C (abbreviated as CPC). From this point of views, the conductive carbon and the solid electrolyte  $\text{PbSnF}_4@ \text{LiF}$  were mixed into cathode in order to increase the ionic and electronic conductors in CPC cathode. A typical high-energy ball milling procedure (with a rotating speed of 600 rpm for 5 h) was implemented for the mixture of commercial anhydrous  $\text{CuF}_2$  (99.99%, Aladdin), as-prepared  $\text{PbSnF}_4@ \text{LiF}$  and Super P with a mass ratio of 3:6:1.

In view of the poor  $\text{F}^-$  ionic conductivity and less reactive interfaces of pure metal anodes, the additional ionic wiring engineering was required to prepare the composite anode of  $\text{Pb}+\text{PbF}_2$ -  $\text{PbSnF}_4@ \text{LiF}$  -C (abbreviated as PPC). This composite anode was prepared by mixing Sn (99.9%, Aladdin),  $\text{SnF}_2$ ,  $\text{KSn}_2\text{F}_5$ , and Super P with a mass ratio of 2.5:2.5:4:1 using the typical high-energy ball milling procedure (with a rotating speed of 600 rpm for 5 h).

*Ionic and Electronic Conduction Estimation of  $\text{PbSnF}_4@ \text{LiF}$ :* putting 120mg  $\text{PbSnF}_4@ \text{LiF}$  inside the metal mold, then pressed it into a pellet with a diameter of 10mm under the pressure of 200 MPa for 2 minutes. Then the construction of ionic blocking layer was executed via blading conductive gold paste on both sides of the pellet, followed by drying at 80 °C for 2 h. Note that, the drying step should be completed under argon protection. Subsequently,  $\text{Au} | \text{PbSnF}_4@ \text{LiF} | \text{Au}$  was assembled into a button cell in order to measure impedance performance though an

electrochemical workstation with a frequency range from 10 MHz to 100 Hz and an excitation voltage of 100 mV. Ionic conductivity can be estimated by equation (3):

$$\sigma = \frac{L}{RS} \quad (3)$$

where L, S, and R denote the thickness, area, and resistance of the pellet, respectively.

*Preparation of Electrodes:* The cathode was prepared by mixing CPC powder, binder poly (vinyl difluoride) (PVDF, Sigma-Aldrich, dissolved in 1-methyl-2-pyrrolidinone, Sinopharm Chemical Reagent Co., Ltd,  $\geq 99.0\%$ , with a mass concentration of 1 mg per 20  $\mu\text{L}$ ) and conductive carbon (Super P, MTI Corporation) with a weight ratio of 7:1:2. The slurry anode was prepared by mixing PPC powder, PVDF, and conductive carbon with a weight ratio of 7:1:2. Then both the cathode and anode slurries were pasted on the pure Al and Cu foils, and then dried at the temperature of 60 °C for 12 h in vacuum.

*Fabrication and Operation of ASSFIBs:* for the better integration of solid -solid interfaces, the THF solution with 1 m TBAF(Aladdin) was used as the interface wetting reagent because the reason that its relative stability and ideal  $\text{F}^-$  conductivity. In the progress during battery assembling, the both sides of the pressured pellet would be dropped about 3  $\mu\text{L}$  TBAF/THF solution to get wet. Then the anode and cathode membranes (both  $\Phi 10$ ) were appressed to each side of the electrolyte pellet surface. LSV test was based on the full cells using above technique. The measurement of electrochemical window of the  $\text{PbSnF}_4@\text{LiF}$  electrolyte would be test in architecture of  $\text{Pb}+\text{PbF}_2|\text{PbSnF}_4@\text{LiF}|\text{PbSnF}_4@\text{LiF}-\text{C}$  cell was also conducted on this

electrochemical workstation at a scan rate of  $1.0 \text{ mV s}^{-1}$ . The as-assembled  $\text{Pb}+\text{PbF}_2 | \text{PbSnF}_4@\text{LiF} | \text{CuF}_2$  cell was placed into an oven at  $80^\circ\text{C}$  for 5 h with the follow-up galvanostatic discharge–charge cycling performance measurement on the Land multichannel battery testing system (CT2001A) at the same temperature. The galvanostatic discharge–charge tests were carried out at a current density of  $60 \text{ mA g}^{-1}$  with a discharge cut-off voltage of  $-0.4 \text{ V}$  (versus  $\text{Pb}/\text{PbF}_2$ ) and a charge cut-off specific capacity of  $300 \text{ mAh g}^{-1}$ .

*Characterization of Materials:* The crystal structure and phase purity of the synthesized materials were studied by powder X-ray diffraction (XRD) using  $\text{Cu K}\alpha 1$  radiation in a  $2\theta$  range from  $10^\circ$  to  $80^\circ$  at a scanning rate of  $10^\circ \text{ min}^{-1}$  to detect the evolution of chemical composition, elemental valence, and bonding situation of the material at different post-reaction states. The samples were sealed using parafilm during measurement to prevent air exposure. The SEM observation was conducted using a SEM (Nova NanoSEM450) scanning electron microscope operated at 3 kV. And the nanostructure of the solid electrolyte interphase (SEI) was examined using transmission electron microscopy (TEM). Note that, for all the ex-situ characterizations, the post-reaction samples were drawn out from the disassembled batteries and then sealed in a bottle in the Ar-filled glove box before the transfer to the corresponding testing chamber.
