#### S1. Mole fractions of precursor oxides and high entropy oxides:

Following Banerjee et al.'s<sup>1</sup> thermodynamic feasibility calculations, several authors<sup>2-5</sup> have used the same approach for their respective high entropy oxides. Table S1 presents the calculated coefficients (a-f and a<sub>1</sub>-f<sub>1</sub>) for Equation 16, governing the thermodynamic transition from precursor oxides to high entropy oxides.

**Table S1:** Mole fractions of precursor oxides (a<sub>1</sub>, b<sub>1</sub>,...,f<sub>1</sub>) and high entropy oxides (a, b,...,f) as described in equation 16.

| Final Product  | Precursors        |         |                   |         |                                |         |                                |         |                                |         |                                |         |

## S2. Mathematical proof of the fact that the possible high entropy alloys will be much more than lower component alloys (such as- binary, ternary alloys etc.):

Let's consider two alloys with the number of elements  $r$  and  $r+1$ . The elements will be selected from  $n$  number of chemical elements.

The formula to calculate the number of ways to choose  $r$  elements from a set of  $n$  elements will be,  $N_1 = C(n, r) = \frac{n!}{r!(n-r)!} \dots$  (S1)

Similarly, when we select  $r+1$  elements from a possible set of  $n$  species, the number of selection will be,  $N_2 = C(n, r+1) = \frac{n!}{(r+1)!(n-(r+1))!} \dots$  (S2)

Let's take the ratio of these two numbers and we obtain:

$$R = \frac{N_1}{N_2} = \frac{C(n, r)}{C(n, r+1)} = \frac{\frac{n!}{r!(n-r)!}}{\frac{n!}{(r+1)!(n-(r+1))!}} = \frac{(r+1)!(n-(r+1))!}{r!(n-r)!} \dots$$
 (S3)

Now, applying the relations  $(r+1)! = (r+1) \times r!$  and  $(n-r)! = (n-r) \times (n-r-1)!$ , we obtain,

$$R = \frac{(r+1)}{(n-r)} \dots$$
 (S4)

If  $r \leq n/2$ , then  $(n-r) > (r+1)$ , or in other words,  $R = \frac{(r+1)}{(n-r)} < 1 \dots$  (S5)

This result indicates that for two alloys — one with  $r$  elements and another with  $r+1$  elements — the number of possible alloys will always be greater for the alloy containing  $r+1$  elements, provided that  $r \leq n/2$ .

Since at least 40 to 50 metallic elements can potentially form high-entropy alloys (HEAs) with 5, 6 or 7 components, the condition  $r \ll n/2$  holds true in the case of HEAs. Consequently, the number of possible HEAs far exceeds that of lower-component alloys, highlighting the vast compositional space available for HEAs compared to traditional binary, ternary, or quaternary alloys.
