Text S1. Evaluation and of catalysts.

The catalyst performance was evaluated in a fixed bed glass microreactor under normal pressure and 180 °C. First, N₂ is injected into the pipeline 30 minutes before the reaction starts to remove residual water and impurity gas. Subsequently, N₂ was switched to HCl gas, which was used to activate the catalyst (3 mL) in the reactor for 30 minutes. When the temperature in the reactor rises to 180 °C, C₂H₂ gas is passed into the reaction system, and the acetylene hydrochlorination reaction begins. The volume ratio of HCl to C₂H₂ ($V_{\text{HCl}}/V_{\text{C}_2\text{H}_2}$) is controlled at = 1.15, and the gas hourly space velocity (GHSV) of acetylene was controlled at 180 h⁻¹. The gaseous product was analyzed quantitatively by gas chromatography after impurity removal and drying. Finally, the performance of the catalyst was evaluated according to the calculated acetylene conversion and vinyl chloride selectivity.

Text S2. Characterization of catalysts.

Programmed Temperature Desorption (TPD) Measurements. The TPD tests were performed on an automated chemisorbent (Quantachrome, Chembet Pulsar TPR/TPD), scanned within the temperature range of 30 to 600 °C with a heating rate of 5 °C/min. For TPD experiments, the samples entirely adsorbed the corresponding gas prior to test.

X-ray Photoelectron Spectroscopy (XPS) Measurement. All spectra were performed on an energy spectrometer containing an Al-K α X-ray source (Thermo Fisher, Escalab 250Xi). The relative data were processed on Advantage. The calibrated energy of C 1s was 248.8 eV.

Programmed Temperature Reduction (H₂-TPR) Measurements. The H₂-TPR tests were performed on an automated chemisorbent (Quantachrome, Chembet Pulsar TPR/TPD).

Accurately weigh 0.1 g of the sample and place it in a U-shaped quartz tube, with both ends filled with an appropriate amount of quartz wool. The flow rate of the 10% H₂/Ar mixed gas was maintained at 100 mL·min⁻¹. The temperature was increased from room temperature to 900 °C at a heating rate of 10 °C·min⁻¹, and TCD signals were recorded throughout this range. The position and area of the hydrogen consumption peak were analyzed to determine the valence state of the active metal species.

Scanning Transmission Electron Microscopy (STEM) Measurements. The separation of metal nanoparticles within the catalyst was examined using a transmission electron microscope (JEOL JEM-F200). Morphology and particle size were analyzed as follows: A small quantity of the sample was ground into powder and placed into a centrifuge tube. An ethanol solution was then added, and the mixture was placed in an ultrasonic bath for uniform dispersion. Subsequently, a small volume of the supernatant was dropped onto a 200/300 mesh grid. The grid was dried under infrared light and examined using the transmission electron microscope at an accelerating voltage of 200 kV.

X-ray Diffraction (XRD) Analysis. X-ray diffraction (XRD) analysis of the catalyst samples was conducted using a Bruker D8 ADVANCE X-ray diffractometer. The operating voltage and current were set at 40 kV and 40 mA, respectively, with a scanning speed of 10° per minute over the range of $2\theta = 10-90^\circ$. Data collection aimed to analyze the variations in the crystal phase structure of metals present in the samples.

Thermogravimetric Analysis (TGA). Thermogravimetric experiments were carried out using a Netzsch STA 449 F5 thermal analyzer. Initially, approximately 10 mg of sample was

loaded. Subsequently, under an air atmosphere with a flow rate of 50 mL/min, the temperature was increased gradually from 25 °C to 900 °C at a heating rate of 10 °C/min. During this process, thermogravimetric (TG) and derivative thermogravimetric (DTG) data were collected to analyze the carbon content deposited on the catalyst surface during the reaction.

Fourier transform infrared spectroscopy (FT-IR). FT-IR analysis was performed on a Bruker Vertex70 FT-IR spectrophotometer. A small amount of the sample was ground and then tablets were pressed for scanning. The wavenumber range was set from 400 to 4000 cm^{-1} , and the information on the surface functional groups of the sample was obtained. *In-situ* diffuse reflection infrared Fourier transform spectroscopy (DRIFTS): The *in-situ* DRIFTS of catalysts was performed using a Bruker Vertex70 FT-IR spectrophotometer with a DTGS detector. The total gas flow was controlled at 5 mL/min. The volume ratio and temperature were controlled as same as the reaction conditions. The temperature was controlled at 180°C. The test spectrum was adjusted to 3000-3500 cm^{-1} .

Text S3. Density functional theory calculation.

The density functional theory (DFT) calculations were carried out with the Materials Studio (MS). The structural optimization adopts the Dmol3 module in Materials Studio, The Becke-Lee-Yang-Parr (BLYP) functional within generalized gradient approximation (GGA) was used to process the exchange-correlation, which was utilized to describe the expansion of the electronic eigenfunctions [1]. All atoms are fully relaxed until the force, displacement, energy, and difference are less than 0.002 Ha/Å, 0.005 Å, 10^{-5} Ha, respectively. Open the charge density preprocessing option and set the maximum value of Subspace Iterative Inverse (DIIS) to 6 to

significantly improve self-consistent field convergence. We analyze the electron transfer process through three distinct approaches: calculating the atomic charge numbers, determining the Hamiltonian population of the crystal orbitals, and examining the projected density of states.

The adsorption energy (E_{ads}) of a complex formed between two molecules, A and B, can be calculated using the following equation:

$$E_{ads} = E_{complex} - (E_A + E_B) \quad (S1)$$

where $E_{complex}$ is the total energy of the molecular complex of A and B. E_A is the energy of the ligand, E_B is the energy of hydrogen chloride or acetylene, respectively.

The formation energy (E_f) of copper clusters can be calculated by the following formula:

$$E_f = E_{cluster} - (E_{Cu} * n_{Cu} + E_{Cl} * n_{Cl}) \quad (S2)$$

where $E_{cluster}$ is the total energy of the copper cluster, E_{Cu} is the energy of the copper atom, and E_{Cl} is the energy of the chlorine atom. The n_{Cu} represents the number of copper atoms, and n_{Cl} represents the number of chlorine atoms

Text S4. Calculations of conversion, selectivity and deactivation rate.

Four indicators, including conversion, selectivity, deactivation rate [2], in this manuscript were used to evaluate the catalytic performances and the detailed calculations were as follows:

$$Conversion (\%) = \frac{C_{inlet} - C_{outlet}}{C_{inlet}} \times 100 \quad (S3)$$

$$\text{Selectivity (\%)} = \frac{C_{C_2H_3Cl}}{C_{inlet} - C_{outlet}} \times 100 \quad (\text{S4})$$

$$\text{Deactivation rate (h}^{-1}\text{)} = \frac{\text{Conversion}_{max} - \text{Conversion}_t}{\Delta t_1} \quad (\text{S5})$$

where C_{inlet} and C_{outlet} represent the concentration of C_2H_2 at the inlet and outlet of reactor, respectively. $C_{C_2H_3Cl}$ is the concentration of C_2H_3Cl at the outlet of reactor, Conversion_{max} is the maximum C_2H_2 conversion, Conversion_t is the last C_2H_2 conversion in the experiment, and Δt_1 is the time taken for conversion to decrease from maximum to residual levels.

Table S1. The content of copper species in the catalyst based on the Cu LMM region.

Catalysts	Cu species (%)			Kinetic energy (eV)		
	Cu ²⁺	Cu ⁺	Cu ⁰	Cu ²⁺	Cu ⁺	Cu ⁰
Cu ₈ PPA ₁ /AC	68.5	19.9	11.6	915.57	910.92	918.82
Cu ₈ BPDC ₁ /AC	67.0	17.5	15.5	915.46	910.79	918.80
Cu ₈ PTDC ₁ /AC	67.6	20.9	11.5	915.37	910.82	918.67

Table S2. The adsorption capacity of different catalysts for HCl and C₂H₂ based on TPD curve.

Catalysts	The adsorption area for HCl			The adsorption area for C ₂ H ₂		
	2:1	8:1	40:1	2:1	8:1	40:1
Cu/AC		100%			100%	
Cu-PPA	388%	189%	247%	70%	68%	75%
Cu-BPDC	246%	117%	147%	111%	63%	58%
Cu-PTDC	330%	328%	367%	99%	58%	63%

Note: The integrated area of the TPD profile for the reference Cu catalyst was defined as 100%, and the areas of all other catalysts were normalized accordingly.
