1. The crystal structure information of Ba₂REV₃O₁₁ (RE = Pr, Nd, Gd-Ho)

Room temperature experimental and refined powder X-ray diffraction (XRD) spectra for the synthesized Ba₂REV₃O₁₁ (RE = Pr, Nd, Gd-Ho) samples are shown in Figure S1, and all the diffraction peaks can be indexed by the monoclinic structure with *P21/a* space group without any detected impurity phases. The calculated XRD patterns match well with the experimental data with small values of reliability factors R_p (4.94-3.86) and R_{wp} (5.83-4.56). From the structure refinements, the extracted structural parameters are listed in Table S1 and S2.

2. The low temperature dc and ac magnetic susceptibility of Ba₂DyV₃O₁₁

The low temperature magnetic susceptibility $\chi(T)$ curves under different fields from 0.05 T to 0.3 T for Ba₂DyV₃O₁₁ are shown in Figure S2. As seen, the $\chi(T)$ measured at low fields show a magnetic anomaly at ~ 3.0 K. From the differential magnetic susceptibility $d\chi/dT$ curves shown in Figure S2(b), the transition peak is determined to be at ~ 2.9 K. To further confirm the existence of magnetic transition, the real part of ac susceptibility curves of Ba₂DyV₃O₁₁ at various frequencies are presented in Figure S3(a). The broad peak maximized at $T_p \sim 3.0$ K is observed, which shows weak frequency dependence indicative of long range magnetic order. Also, the specific heat reveals a clear λ -like anomaly at ~ 2.9 K. Below ~ 2.9 K, the heat capacity continues to rise possibly due to the presence of an additional magnetic transition at lower temperatures, similar to observations in other RE-based magnets reported in Ho₃Al₅O₁₂ and DyBO₃ compounds^{1,2}.
