## Experimental Section

### Materials

2,4,6-triformylphloroglucinol (Tp) was purchased from Aladdin. 2,5-diaminobenzenesulfonic acid (Pa-SO<sub>3</sub>H) was obtained from Macklin. KCl (≥ 99.8%), NaCl (≥ 99.8%), LiCl (≥ 99.0%), MgCl<sub>2</sub>·6H<sub>2</sub>O (≥ 99.0%), CaCl<sub>2</sub> (≥ 96%) and LaCl<sub>3</sub>·6H<sub>2</sub>O (≥ 99.99%) were purchased from Aladdin. PTFE microporous membranes were purchased from MREDA. All other reagents were obtained from Beijing Chemical Works.

### Synthesis of the TpPa-SO<sub>3</sub>H covalent organic framework (COF) membrane

First, a 3 mM aqueous solution of Pa-SO<sub>3</sub>H containing 3 M acetic acid was poured into a funnel. A PTFE substrate was tilted at a 15° angle and immersed in the aqueous phase. Subsequently, a 2 mM toluene solution of Tp was slowly added to form a sharp and stable interface between the organic phase and the aqueous phase. After injection, the two monomers gradually polymerized at the interface over three days at room temperature, yielding a macroscopic orange-red membrane. After the reaction, slowly drained the solution was drained from the funnel, allowing the COF membrane to gradually deposit onto the substrate. The resulting membrane was dried at ambient temperature and carefully rinsed with methanol.

### Calculation of Critical Inversion Concentration (c<sub>rc</sub>)

Mean-field theory is commonly applied to describe the diffusion layer, while strongly correlated liquids (SCL) theory is employed to model ion-surface and ion-ion interactions within the Stern layer. The SCL theory provides an analytical prediction for the critical ion concentration at which charge inversion occurs<sup>1-4</sup>:

$$c_{crc} = \left| \frac{\sigma_b}{2r_{ion}Ze} \right| \exp\left(\frac{\mu_c}{k_B T}\right)$$

The electrochemical potentials of Z-valent ions in the bulk and the Stern layer are given by<sup>2,5</sup>:

$$\mu_b = \mu_b^0 + k_B T \ln C_{b,0} + Ze\varphi_\infty$$

$$\mu_s = \mu_s^0 + k_B T \ln\left(\frac{n}{2r_{ion}}\right) + Ze\varphi_s$$

where  $C_{b,0}$  is the bulk concentration of Z-ion.  $\varphi_\infty$  and  $\varphi_s$  are the electrochemical potentials of the bulk phase and the Stern layer, respectively. In a state of equilibrium,  $\mu_b = \mu_s$  and  $\varphi_\infty = 0$ , yielding:

$$\mu_0 + k_B T \ln C_{b,0} = k_B T \ln\left(\frac{n}{2r_{ion}}\right) + Ze\varphi_s$$

Among them,  $\mu_0 = \mu_i + \mu_c$  includes all ion-surface interactions, where  $\mu_i$  accounts for hydration and specific binding effects, and  $\mu_c$  is the chemical potential arising from ion correlations, given by<sup>1-3</sup>:

$$\mu_c = -k_B T (1.65\Gamma - 2.61\Gamma^{\frac{1}{4}} + 0.26\ln\Gamma + 1.95)$$

In SCL theory, ion correlation is considered the primary cause of charge inversion. The coupling parameter  $\Gamma$  is defined as:

$$\Gamma = \frac{1}{4k_B T \varepsilon_f \sqrt{\pi}} \sqrt{|e^3 Z^3 \sigma_b|}$$

### Preparation of COF powder

Tp (169.4 mg) and Pa-SO<sub>3</sub>H (126.0 mg) were weighed into a Pyrex tube. Add 3 mL of as A mixed solvent system of n-butanol (3 mL) and o-dichlorobenzene (3 mL) was added, followed by 1.2 mL of acetic acid aqueous solution (6 M) as the reaction catalyst.<sup>6</sup> After ultrasonic dispersion for 2 minutes, completely immerse the reaction system in

liquid nitrogen until fully solidified. The tube was evacuated and slowly warmed to room temperature to release dissolved gases. This freeze-thaw cycle was repeated three times. The sealed tube was heated in silicone oil at 120°C for 72 hours. After reaction, the product was collected by filtration, washed thoroughly with ethanol and tetrahydrofuran (THF), and finally dried under vacuum at 100°C for 12 hours to obtain a red powder.

### **Calculation of K<sup>+</sup> adsorption by COF**

The K<sup>+</sup> adsorption capacity was calculated by the following equation<sup>7</sup>:

$$Capacity = \frac{(C_0 - C_e)V}{m}$$

To account for weakly adsorbed K<sup>+</sup>, the TpPa-SO<sub>3</sub>H powder was washed ten times with 10 mL of deionized water. The ion concentration in the combined filtrate was measured, and the amount of residual K<sup>+</sup> was subtracted to determine the net adsorption capacity, which was calculated to be 0.285 mmol g<sup>-1</sup>. The BET surface area of TpPa-SO<sub>3</sub>H is 113.27 m<sup>2</sup>/g, with an average pore size of 1.27 nm. From this, the number of nanopores was estimated, indicating that each nanopore captured approximately 3.2 K<sup>+</sup> ions on average.

## Table of Contents

- Supplementary Figure S1: Synthesis scheme and molecular structure of TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S2: FTIR spectra of TpPa-SO<sub>3</sub>H powders.
- Supplementary Figure S3: Raman spectroscopy of TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S4: XPS spectra of TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S5: SEM-EDS elemental mapping of the TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S6: AFM height image and corresponding profile of TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S7: N<sub>2</sub> adsorption-desorption isotherms of TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S8: Water contact angle measurement of the TpPa-SO<sub>3</sub>H membrane.
- Supplementary Figure S9: Ion selectivity measurements in KCl, LiCl, CaCl<sub>2</sub> and Na<sub>2</sub>SO<sub>4</sub> solutions.
- Supplementary Figure S10: Fitting curves of  $V_{OC}$  and  $C_H$ .
- Supplementary Figure S11: Current-voltage ( $I$ - $V$ ) curves measured as a function of pH.
- Supplementary Figure S12: Concentration of K<sup>+</sup> in the filtrate as a function of washing cycles.
- Supplementary Table S1: Tested ionic species and their corresponding bare radii, hydrated radii, and hydration energies.
