Abstract: Two enantiomeric Schiff base ligands $R-/ S-\mathrm{H}_{2} \mathbf{L}$ in situ generated from the condensation of $o$ vanillin with $R$ - or $S$-2-phenylglycinol were applied to assemble chiral multinuclear transition metal magnetic clusters for the first time. Four new enantiomerically pure chiral clusters, $\left[\mathrm{NaMn}_{4}\left(\mu_{3^{-}}\right.\right.$ $\left.\mathrm{O})\left(\mathrm{N}_{3}\right)_{1.75} \mathrm{Br}_{0.25}(R-\mathrm{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{2}(R-\mathrm{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{Br}_{4} \quad(\mathbf{1 R}), \quad\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\right.\right.$ $\left.\mathrm{O})\left(\mathrm{N}_{3}\right)_{1.75} \mathrm{Br}_{0.25}(S-\mathrm{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{2}(S-\mathbf{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{Br}_{4} \quad(\mathbf{1 S}), \quad\left[\mathrm{Cu}_{6}(R-\mathbf{L})_{2}(R-\right.$ $\left.\mathbf{H L})_{2}\left(\mathrm{~N}_{3}\right)_{5}(\mathrm{MeOH})\right] \mathrm{NO}_{3} \cdot 2 \mathrm{MeOH} \cdot \mathrm{H}_{2} \mathrm{O} \quad(\mathbf{2 R})$ and $\left[\mathrm{Cu}_{6}(\mathrm{~S}-\mathrm{L})_{2}(\mathrm{~S}-\mathrm{HL})_{2}\left(\mathrm{~N}_{3}\right)_{5}(\mathrm{MeOH})\right] \mathrm{NO}_{3} \cdot 2 \mathrm{MeOH} \cdot \mathrm{H}_{2} \mathrm{O} \quad(\mathbf{2 S})$, have been synthesized and characterized by single crystal X-ray crystallography and CD spectroscopy.. Three $\mathrm{Mn}(\mathrm{III})$ in the $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ clusters of $\mathbf{1 R}$ and $\mathbf{1 S}$ are joined together through the $\mu_{3}-\mathrm{O}$ bridge to form an oxo-centered $\mathrm{Mn}_{3} \mathrm{O}$ unit. Three $\mathbf{L}^{2-}$ link four manganese atoms via the $\mu_{2}-O, N, O$-bridging manner into a $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ cluster in a distorted tetrahedral geometry. Enantiomeric 2S and 2R are hexanuclear copper(II) clusters composed of a cubane-like $\mathrm{Cu}_{4} \mathbf{L}_{4}$ part with a dinuclear $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$ unit capped on one of the faces of the $\mathrm{Cu}_{4} \mathbf{L}_{4}$ cubane via the $\mu_{1,1}$-azide and phenolate bridges from the chiral ligands. Magnetic analysis reveals intracluster antiferromagnetic interaction between adjacent manganese ions in chiral oxo-centered $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ magnetic clusters for $\mathbf{1 R}$ and $\mathbf{1 S}$, and dominating antiferromagnetic over weak ferromagnetic interactions in $\mathrm{Cu}_{6}$ clusters in $2 \mathbf{R}$ and $2 \mathbf{S}$.

## Introduction

Chirality is of great significance in biology, chemistry and materials science. Chiral coordination compounds have attracted much attention owing to their specific physical/chemical properties in optical materials, enantioselective synthesis and asymmetric catalysis. ${ }^{1}$ The observation of magneto-chiral dichroism (MChD) effect from chiral paramagnetic compounds ${ }^{2}$ has urged materials scientists to prepare new multifunctional molecular materials of both chirality and magnetism coexisting within one molecule. Since the pioneering work on a family of single-molecule magnets (SMMs) with $\mu_{3}$-O-centered manganese clusters was reported by Christou, Brechin and co-workers, ${ }^{3,4 a, c-g}$ there have been great interest in polynuclear oxo-centered metal complexes, especially in manganese clusters as SMMs in the last two decades. ${ }^{3-5}$ However only several oxo-centered manganese clusters crystallized in chiral space groups have been found, ${ }^{6 a}$ yet fewer of them were revealed with naturally optical activity. ${ }^{6 b}$ It is still a challenge to synthesize enantiopure transition metal clusters because of the difficulties in controlling chirality within the molecular structures and throughout the entire supramolecular networks. ${ }^{7,8}$

We have successfully prepared a series of manganese clusters by the utilization of some achiral aminoalcohol ligands such as triethanolamine (teaH3) and $N, N, N^{\prime}, N^{\prime}$-tetrakis(2-hydroxyethyl) ethylenediamine $\left(e^{2}+\mathrm{H}_{4}\right)$, including an unprecedented giant heterometallic $\mathrm{Cu}_{17} \mathrm{Mn}_{28}$ cluster $\left[\mathrm{Cu}_{17} \mathrm{Mn}_{28} \mathrm{O}_{40}(\text { tea })_{12}\left(\mathrm{HCO}_{2}\right)_{6}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot 36 \mathrm{H}_{2} \mathrm{O}$ with a $S={ }^{51} / 2$ ground state in low magnetic field, ${ }^{9 \mathrm{a}}$ a novel family of $\mathrm{Mn}_{12}$ clusters incorporating the same $\mathrm{Mn}_{12} \mathrm{O}_{4}$ cores and the tunable oxidation states of $\mathrm{Mn}^{\mathrm{III}}{ }_{x} \mathrm{Mn}^{\mathrm{II}}{ }_{12-x}(x=8,10$ and 12$)$ with the increasing $S_{\mathrm{T}}$ values versus the increasing quantity of $\mathrm{Mn}^{\mathrm{III}}$ ions, ${ }^{96}$ and an unusual ferromagnetic tetranuclear $\mathrm{Mn}^{\mathrm{II}}{ }_{2} \mathrm{Mn}^{\mathrm{IV}}{ }_{2}$ compound with $S_{\mathrm{T}}=8 .{ }^{9 \mathrm{c}}$ To further extend the studies on transition metal clusters, we now focus on the transition metal chemistry of chiral schiff base ligands. Schiff base metal complexes are a class of compounds that have been studied extensively due to their attractive physical/chemical properties and their wide-ranging applications. ${ }^{10}$ Salicylaldehyde derivated Schiff bases, which are potentially multi-dentate and hydroxyl-rich ligands, have not well been exploited for the preparation of polynuclear complexes. ${ }^{11,12}$ Herein we report the synthesis, structures and magnetic properties of two enantiomorphic oxo-centered $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ compounds, $\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{1.75} \mathrm{Br}_{0.25}(R-\right.$
$\left.\mathbf{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{2}(R-\mathbf{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{Br}_{4}(\mathbf{1 R})$ and $\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{1.75} \mathrm{Br}_{0.25}(S-\right.$ $\left.\mathbf{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\mathrm{NaMn}_{4}\left(\mu_{3}-\mathrm{O}\right)\left(\mathrm{N}_{3}\right)_{2}(\mathrm{~S}-\mathrm{L})_{3}(\mathrm{MeOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{Br}_{4}(\mathbf{1 S})$, and two enantiomorphic $\mathrm{Cu}^{\mathrm{II}}{ }_{6}$ compounds, $\quad\left[\mathrm{Cu}_{6}(R-\mathbf{L})_{2}(R-\mathrm{HL})_{2}\left(\mathrm{~N}_{3}\right)_{5}(\mathrm{MeOH})\right] \mathrm{NO}_{3} \cdot 2 \mathrm{MeOH} \cdot \mathrm{H}_{2} \mathrm{O} \quad$ (2R) and $\quad\left[\mathrm{Cu}_{6}(S-\mathrm{L})_{2}(S-\right.$ $\left.\mathrm{HL})_{2}\left(\mathrm{~N}_{3}\right)_{5}(\mathrm{MeOH})\right] \mathrm{NO}_{3} \cdot 2 \mathrm{MeOH} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{2 S})$. The chiral ligands $R-/ S-\mathrm{H}_{2} \mathbf{L}$ (Scheme 1) in the four compounds were derived from the in situ condensation reaction of $o$-vanillin with $(R)-(-)$ - or $(S)-(+)-2$-phenylglycinol, respectively.

## Experimental Section

Materials and Physical Measurements The reagents and solvents used were commercially available and used as received without further purification. The Schiff-base ligands $R-\mathrm{H}_{2} \mathbf{L}$ and $S-\mathrm{H}_{2} \mathbf{L}$ were in situ generated from the condensation of $o$-vanillin with $(R)-(-)-2$-phenylglycinol or $(S)-(+)-2$-phenylglycinol, respectively. C, H, and N microanalyses were carried out with Elementar Vario-EL CHN elemental analyzer. FT-IR spectra were recorded in KBr tablets in the range of $4000-400 \mathrm{~cm}^{-1}$ on Bio-Rad FTS-7 spectrometer. Variable-temperature magnetic susceptibility measurements were carried out using SQUID magnetometer MPMS XL-7 (Quantum Design) at 0.1T for 1R, 1S, 2R and 2S. Diamagnetic correction was applied from Pascal's constants. The circular dichroism spectra were recorded on a JASCO J-810 Spectropolarimeter in KBr pellets. The UV-vis spectra were measured on a $\mathrm{J} \Lambda \mathrm{SCO} \mathrm{V}-570$ spectrophotometer.

Caution Azido complexes are potentially explosive, especially in the presence of organic ligands. Therefore these compounds must be handled with care and prepared only in small amounts.

Synthesis of 1R or 1S. The mixture of $o$-vanillin ( 0.2 mmol ), ( $R$ )-(-)-2-phenylglycinol $(0.2 \mathrm{mmol}) /(S)$ -$(+)$-2-phenylglycinol $(0.2 \mathrm{mmol})$ and $\mathrm{NaN}_{3}(0.8 \mathrm{mmol}, 0.052 \mathrm{~g})$ was added to the methanolic solution ( 10 $\mathrm{mL})$ of $\mathrm{MnBr}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.8 \mathrm{mmol}, 0.229 \mathrm{~g})$ at room temperature. A clear solution in brown color was yielded after stirring for 2 hours. The resulted solution was allowed to evaporate slowly in air. Well-shaped black crystals of $\mathbf{1 R}$ or $\mathbf{1 S}$ were collected in one week. Yield: $61 \mathrm{mg}(63 \%)$ for $\mathbf{1 R}$ and $63 \mathrm{mg}(65 \%)$ for $\mathbf{1 S}$. Elemental analysis calcd (\%) for $\mathrm{C}_{102} \mathrm{H}_{122} \mathrm{Br}_{4.25} \mathrm{Mn}_{8} \mathrm{~N}_{17.25} \mathrm{Na}_{2} \mathrm{O}_{30}$ (1R): $\mathrm{C}, 42.32 ; \mathrm{H}, 4.25$; $\mathrm{N}, 8.35$; found (\%): C, 41.92; H, 4.39; N, 8.73\%. IR ( $\mathrm{KBr} \mathrm{cm}^{-1}$ ): 3408 (br), 2051 (s), 1618 (s), 1384 (s), 1020 (m), 642 (w).

Elemental analysis calcd (\%) for $\mathrm{C}_{102} \mathrm{H}_{122} \mathrm{Br}_{4.25} \mathrm{Mn}_{8} \mathrm{~N}_{17.25} \mathrm{Na}_{2} \mathrm{O}_{30}$ (1S): C, 42.32 ; H, 4.25; $\mathrm{N}, 8.35$; found (\%):C, 42.18, H 4.31, N 8.80\%.

Synthesis of $2 \boldsymbol{R}$ or $2 S$. The mixture of $o$-vanillin ( 0.2 mmol ), ( $R$ )-(-)-2-phenylglycinol ( 0.2 mmol$) /(S)$ -$(+)$-2-phenylglycinol $(0.2 \mathrm{mmol})$ and $\mathrm{NaN}_{3}(0.5 \mathrm{mmol}, 0.039 \mathrm{~g})$ was added to the methanolic solution ( 10 $\mathrm{mL})$ of $\mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.3 \mathrm{mmol}, 0.075 \mathrm{~g})$ and $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.2 \mathrm{mmol}, 0.048 \mathrm{~g})$ at room temperature. A dark-green solution was observed after stirring for 2 hours and allowed to evaporate slowly in air. Wellshaped dark green crystals of $\mathbf{2 R}$ or $\mathbf{2 S}$ were collected in three days. Yield: 19 mg (31\%) for $\mathbf{2 R}$ and 21 mg (34\%) for 2S. Elemental analysis calcd (\%) for $\mathrm{C}_{67} \mathrm{H}_{76} \mathrm{Cu}_{6} \mathrm{~N}_{20} \mathrm{O}_{19}(\mathbf{2 R})$ : C, $43.58 ; \mathrm{H}, 4.15 ; \mathrm{N}, 15.17$; found (\%): C, 43.09; H, 3.95; N, 15.46\%. IR ( $\mathrm{KBr} \mathrm{cm}^{-1}$ ): 3423 (br), 2075 (s), 1637 (s), 1384 (m), 1171 (s), 742 (m). Elemental analysis calcd (\%) for $\mathrm{C}_{67} \mathrm{H}_{76} \mathrm{Cu}_{6} \mathrm{~N}_{20} \mathrm{O}_{19}$ (2S): C, 43.58; H, 4.15; N, 15.17; found (\%):C, 43.41, H, 4.00, N, 15.41\%.

X-ray Crystallography Diffraction data were recorded on Oxford Diffraction Gemini R CCD diffractometer with $\mathrm{Cu} \mathrm{K} \alpha$ radiation ( $\lambda=1.54178 \AA$ ) for 1R, $\mathbf{1 S}$ and $\mathbf{2 S}$ and on Bruker Apex CCD area detector diffractometer with $\mathrm{Mo} \mathrm{K} \alpha$ radiation $(\lambda=0.71073 \AA$ ) for $\mathbf{2 R}$ at 150 K . The temperature of measurement was controlled using Oxford Cryosystems Cryostream cooling apparatus. The data procession was accomplished with the program SAINT; absorption correction based on symmetry equivalent reflections was applied using the SADABS program for 2 R. ${ }^{13 a}$ The data collection routine, unit cell refinement, and data processing were carried out with the program CrysAlisPro for $\mathbf{1 S}, \mathbf{1 R}$ and $\mathbf{2 S}$. ${ }^{13 b}$ The structures were solved by direct method and all non-hydrogen atoms were refined anisotropically by fullmatrix least-squares techniques using the SHELXTL program. ${ }^{14}$ The hydrogen atoms on the organic motifs were added on calculated positions and refined with isotropic thermal parameters riding on those of the parent atoms. These idealized H atoms had their isotropic temperature factors fixed at 1.2 or 1.5 times the equivalent isotropic $U$ of the parent $C$ atoms to which they were bonded. Further details for structural analysis for compounds $\mathbf{1 R}, \mathbf{1 S}, \mathbf{2 S}$ and $\mathbf{2 R}$ are summarized in Table 1. Bond distances and angles are listed in Tables S1 and S2 in the Supporting Information.

## Results and Discussion

## Synthesis.

Both $\mathbf{1 R}$ and $\mathbf{1 S}$ contain the $\mathrm{Mn}^{\text {III }}$ ions. Given that the starting Mn sources were exclusively $\mathrm{Mn}^{\mathrm{II}}$ ions, it is apparent that the $\mathrm{Mn}^{\text {III }}$ ions were generated upon the oxidation by atmospheric $\mathrm{O}_{2}$, a process very common in manganese cluster chemistry even in solvents with moderate reducibility. ${ }^{12}$ There are $\mathrm{N}_{3} / \mathrm{Br}^{-}$disorder observed in the structures, but we have tried in vain to replace $\mathrm{Br}^{-}$ion and avoid the disorder by increasing the amount of $\mathrm{N}_{3}{ }^{-}$to 1.0 mmol or starting from manganese salts with weakly-coordinated anions such as $\mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$. The combination of $\mathrm{MnBr}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O} / \mathrm{NaN}_{3}$ as the metal sources and Lewis bases seemingly works the best to yield the clusters. When $\mathrm{Mn}(\mathrm{OAc})_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O} / \mathrm{NaOAc} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ were used in the reaction where the acetate was expected to take the place of the bridging $\mathrm{N}_{3} / \mathrm{Br}^{-}$, or when $\mathrm{MnBr}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O} / \mathrm{Et}_{3} \mathrm{~N}$ were involved where the manganese cations, $\mathrm{Mn}(\mathrm{III})$ or Mn (II), was supposed to replace the sodium ion, only amorphous powder were yielded.

It should be noted that $\mathrm{Mn}(\mathrm{II})$ salt is the necessary for the synthesis of compounds $\mathbf{2 R}$ and $\mathbf{2 S}$ though the component of final products do not contain any Mn element. Only amorphous power precipitate was obtained in the absence of manganese(II) salts.

## Crystal structures

Structures of 1 R and 1S. X-ray single crystal structure analysis reveals that $\mathbf{1 R}$ and $\mathbf{1 S}$ are enantiomeric to each other and crystallize in monoclinic space group $P 2_{1}$. There are two cationic $\mathrm{Mn}_{4}$ cluster units and four $\mathrm{Br}^{-}$anions within an asymmetric unit (Figure 1a) in $\mathbf{1 R} / \mathbf{1 S}$. The two manganese clusters are almost the same except that in the first cluster one azide in an end-on mode is connected between two $\mathrm{Mn}^{\mathrm{III}}$ atoms while in the second manganese cluster, there is some disorder on the bridge ligands between two $\mathrm{Mn}^{\mathrm{II}}$ ions with $75 \%$ end-on azide and $25 \% \mu_{2}$-bromide ions occupancy. Each manganese cluster is composed of four crystallographically unique Mn atoms, three $\mathrm{Mn}^{\mathrm{III}}$ and one $\mathrm{Mn}^{\mathrm{II}}$. In one of the clusters, the $\mathrm{Mn}^{\mathrm{III}}$ atoms, $\mathrm{Mn} 1, \mathrm{Mn} 2$ and Mn 3 , are joined together through the $\mu_{3}-\mathrm{O}$ bridge to form an oxo-centered $\mathrm{Mn}_{3} \mathrm{O}$ unit. Mn 1
and Mn3 have almost the same coordination environments in slightly distorted octahedral geometry surrounded with one $R-\mathrm{L}^{2-}$ via $O, N, O$-chelation, one $\mu_{3}-\mathrm{O}$ atom, one $\mu_{2}-\mathrm{MeOH}$ and one $\mathrm{N}_{3}-{ }^{-} / \mathrm{Br}^{-}$ion ( $\mathrm{Mnl}-\mathrm{O}$ $=1.850(9)-2.505(11) \AA, \mathrm{Mn} 1-\mathrm{N}(\mathrm{Br})=1.967(13)-2.828(7) \AA, \mathrm{Mn} 3-\mathrm{O}=1.884(11)-2.592(11) \AA, \mathrm{Mn} 3-\mathrm{N}(\mathrm{Br})$ $=2.001(13)-2.661(7) \AA$ ). Mn2 is adapted in an octahedral geometry coordinated with one $\mu_{3}-\mathrm{O}$, two $\mu_{2^{-}}$ MeOH and one $O, N, O-$ dentate $R-\mathrm{L}\left(\mathrm{Mn} 2-\mathrm{O}=1.847(9)-2.473(12) \AA\right.$, Mn2-N $=1.956(11) \AA$ ). Two $\mu_{2^{-}}$ MeOHs and one $\mu_{2}-\mathrm{N}_{3}{ }^{-}$bridging help the $\mathrm{Mn}_{3} \mathrm{O}$ core to retain the trigonal geometry. The only $\mathrm{Mn}^{\mathrm{II}}$ atom, Mn4, shows a slightly distorted octahedral geometry connected by three $\mu_{2}-\mathrm{O}$ atoms from three $R$ - $\mathrm{L}^{2-}$ ligands ( $\mathrm{Mn} 4-\mathrm{O}=2.168(11)-2.201(10) \AA$ ), two water molecules $(\mathrm{Mn} 4-\mathrm{O}=2.256(12)-2.260(13) \AA$ ) and one $\mathrm{N}_{3}{ }^{-}(\mathrm{Mn} 4-\mathrm{N}=2.178(15) \AA)$. The chirality of the organic ligands was retained during the reactions and the six $\mathbf{L s}$ in the asymmetric unit are in the same handedness. Three $R-\mathbf{L}^{2-}$ link four manganese atoms via the $\mu_{2^{-}}$ $O, N, O$-bridging manner into a $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ cluster in a distorted tetrahedral geometry (Figure 1b). The sodium atom is encapsulated by the deprotonated hydroxyl groups and the methoxyl groups on the tails of three $R$ Ls beneath the tetrahedral $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ core and thus forms a trigonal bipyramidal $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3} \mathrm{Na}$ cluster.

## Structures of 2R and 2S

Enantiomeric compounds $\mathbf{2 R}$ and $\mathbf{2 S}$ crystallize in orthorhombic space group $P 2_{1} 2_{1} 2_{1}$. The asymmetric unit contains one discrete hexanuclear $\mathrm{Cu}_{6}$ cluster cation, one $\mathrm{NO}_{3}{ }^{-}$counterion, one lattice water and two solvated methanol molecules (Figure 2). The cationic $\mathrm{Cu}_{6}$ core is composed of six crystallographically unique Cu atoms on general positions, two completely deprotoned $\mathbf{L}^{2-}$ and two mono-deprotonated $\mathrm{HL}^{-}$ ligands, three end-on and two terminal $\mathrm{N}_{3}{ }^{-}$and one coordinated methanol molecule. The $\mathrm{Cu} 1, \mathrm{Cu} 4$ and Cu 5 have the similar elongated $[4+1]$ square pyramidal geometry. Cul is surrounded with one monodeprotonated $\mathbf{H L}^{-}$via the $O, N, O$-chelation, one $\mathbf{L}^{2-}$ via the deprotonated $\mu_{3}$-hydroxide and one methanol molecule $\left(\mathrm{Cu} 1-\mathrm{O}_{R-\mathrm{L}}=1.930(6)-1.990(6) \AA, \mathrm{Cu}-\mathrm{O}_{\mathrm{MeOH}}=2.233(7) \AA, \mathrm{Cu} 1-\mathrm{N}_{R-\mathrm{L}}=1.940(7) \AA\right.$ for 2R; Cu1-$\mathrm{O}_{S-\mathrm{L}}=1.938(4)-1.991(4) \AA, \mathrm{Cu} 1-\mathrm{O}_{\mathrm{MeOH}}=2.243(4) \AA, \mathrm{Cu} 1-\mathrm{N}_{S-\mathrm{L}}=1.943(5) \AA$ for 2S). Cu 4 has the similar coordination environment except that the methanol is replaced with the end-on azide ( $\mathrm{Cu} 4-\mathrm{O}=1.948$ (6)$1.975(6) \AA, \mathrm{Cu} 4-\mathrm{N}_{R-\mathrm{L}}=1.933(7) \AA$ and $\mathrm{Cu} 4-\mathrm{N}_{\text {azide }}=2.299(8) \AA$ for $\mathbf{2 R} ; \mathrm{Cu} 4-\mathrm{O}=1.935(4)-1.987(4) \AA, \mathrm{Cu} 4-$ $\mathrm{N}_{S-\mathrm{L}}=1.949(5) \AA$ and $\mathrm{Cu} 4-\mathrm{N}_{\mathrm{azide}}=2.306(5) \AA$ for $\left.\mathbf{2 S}\right) . \mathrm{Cu} 5$ is connected with one deprotoned $\mathbf{L}^{2-}$ via the
$O, O$-chelation and three end-on azides $\left(\mathrm{Cu} 5-\mathrm{O}_{R-\mathrm{L}}=2.009(6)\right.$ and $2.288(7) \AA, \mathrm{Cu} 5-\mathrm{N}_{\mathrm{azi} i d e}=1.946(8)-2.000(8)$ $\AA$ for 2R; $\mathrm{Cu} 5-\mathrm{O}_{S-\mathrm{L}}=2.024(4)$ and $2.275(5) \AA, \mathrm{Cu} 5-\mathrm{N}_{\mathrm{azide}}=1.958(6)-2.005(6) \AA$ for $\left.\mathbf{2 S}\right)$. The Cu 2 and Cu 3 atoms are in a similar elongated [4+2] octahedral geometry linked with one $\mathrm{HL}^{-}$via $O, O$-chelation and two $\mathbf{L}^{2-}$ via the $O, N, O$-chelation and the $\mu_{3}$-hydroxide $\left(\mathrm{Cu} 2-\mathrm{O}_{R-\mathrm{L}}=1.886(6)-2.548(6) \AA, \mathrm{Cu} 2-\mathrm{N}_{R-\mathrm{L}}=1.941(7) \AA\right.$; $\mathrm{Cu} 3-\mathrm{O}_{R-\mathrm{L}}=1.936(6)-2.466(6) \AA, \mathrm{Cu} 3-\mathrm{N}_{R-\mathrm{L}}=1.925(7) \AA$ for 2R$; \mathrm{Cu} 2-\mathrm{O}_{S-\mathrm{L}}=1.903(4)-2.545(4) \AA, \mathrm{Cu} 2-\mathrm{N}_{S-\mathrm{L}}$ $=1.914(7) \AA ; \mathrm{Cu} 3-\mathrm{O}_{S-\mathrm{L}}=1.947(4)-2.470(4) \AA, \mathrm{Cu} 3-\mathrm{N}_{S-\mathrm{L}}=1.921(5) \AA$ for 2 S$) . \mathrm{Cu} 6$ has a square planar geometry coordinated with two end-on and two terminal azide ligands $\left(\mathrm{Cu} 6-\mathrm{N}_{\text {azide }}=1.943(9)-1.998\right.$ (8) $\AA$ for 2R; $\mathrm{Cu} 6-\mathrm{N}_{\text {azide }}=1.958(7)-2.019(6) \AA$ for $\left.\mathbf{2 S}\right)$. The Cu 5 and Cu 6 are bridged by two $\mu_{1,1}$-azides into a dinuclear $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$ with the $\mathrm{Cu} \cdots \mathrm{Cu}$ distances of $3.092(2)$ for $\mathbf{2 R}$ and $3.102(1) \AA$ for $\mathbf{2 S}$, respectively. Both $\mathrm{HL}^{-}$ligands link two copper centers in $O(H), N, O-$ and $O, O$-chelation fashion while one of the $\mathbf{L}^{2-}$ ligands connects three metal ions in $O, N, O$-chelation and $\mu_{3}-\mathrm{O}$ modes and the other links four copper in a $\mu_{3}-\mathrm{O}, \mu_{3^{-}}$ $O, N, \mu_{2}-O$ - and $\mu_{2}-O, O$-chelation manner. Accordingly the $\mathrm{Cu}_{6}$ cluster can be viewed as constructing from two units: a cubane-like $\mathrm{Cu}_{4} \mathrm{O}_{4}$-containing part with a dinuclear $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$ unit capped on one of the faces of the $\mathrm{Cu}_{4} \mathrm{O}_{4}$ cubane via the $\mu_{1,1}$-azide and phenolate bridges. $\mathrm{The}^{\mathrm{Cu}}{ }^{\cdots} \mathrm{Cu}$ distances within the $\mathrm{Cu}_{4} \mathrm{O}_{4}$ unit are 3.150(2)-3.897(2) for 2R and 3.167(1)-3.900(1) $\AA$ for 2S, respectively. The dihedral angel between the dinuclear $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$ motif and the capped face of $\mathrm{Cu}_{4} \mathrm{O}_{4}$ cubane unit is ca. $5.489^{\circ}$. No symmetric relationship can be found between the copper atoms in either the $\mathrm{Cu}_{4} \mathrm{O}_{4}$ cubane or $\mathrm{Cu}_{6}$ cluster. This is quite different from the previously reported double-capped cubane $\mathrm{Cu}_{6}$ compound, ${ }^{15}$ in which both the cubane and the $\mathrm{Cu}_{6}$ cluster have the $S_{4}$ symmetry.

## Spectroscopic Properties

Enantiopurity of the chiral organic ligands and the resulted coordination compounds was investigated with circular dichroism (CD) spectroscopy. The starting materials, $(R)-(-)-/(S)-(+)-2$-phenylglycinol, exhibit absorption peaks at 260 nm and 270 nm in methanol solution, which are due to $\pi-\pi *$ transitions of benzene rings (Figure S1a). The CD spectra of Schiff base $R-\mathrm{H}_{2} \mathbf{L} / S-\mathrm{H}_{2} \mathbf{L}$ (the mixture of $o$-vanillin and $(R)-(-)-/(S)-$ $(+)$-2-phenylglycinol in molar ratio of 1:1 in methanol) are rather different from those for 2-phenylglycinol, which have the contiguous peaks of the same sign at wavelength of 325 nm and 418 nm (Figure S1b). These
absorption are attributed to $\pi-\pi^{*}$ transitions and $n-\pi^{*}$ transitions originating from the azomethine chromophore of Schiff base $R-\mathrm{H}_{2} \mathbf{L} / S-\mathrm{H}_{2} \mathbf{L}$.

The enantiomeric nature of $\mathbf{1 R}$ and $\mathbf{1 S}$ in solid state was measured using circular dichroism spectroscopy in KBr pellets (Figure 3a). The spectra of $\mathbf{1 R}$ and $\mathbf{1 S}$ are mirror-image to each other. The $R$-enantiomer exhibits a small positive absorption at 260 nm , decreases to a large negative peak at 320 nm and increases again to a positive maximum at 425 nm . The $S$-enantiomer displays absorption peaks of the opposite sign in the same wavelength range. The CD spectra of $\mathbf{1 R}$ and $\mathbf{1 S}$ in methanol solution were also studied, which are similar in shape to those measured in solid state except that the absorption maxima shift to 300 nm and 400 nm for $\mathbf{1 R}$ and $\mathbf{1 S}$ (Figure S1c). The three peaks of $\mathbf{1 R}$ and $\mathbf{1 S}$ both in solid and solution states are attributed to $\pi-\pi^{*}$ transitions of benzene ring, $\pi-\pi *$ transitions and $n-\pi *$ transitions originating from the azomethine chromophore from higher energy region to the lower one.

The circular dichroism (CD) spectra of $\mathbf{2 R}$ and $\mathbf{2 S}$ were measured in KBr pellets as well as in methanol solution (Figure 3b and S1d). The solid state CD spectrum of 2R exhibits three weak positive absorption peaks at $265 \mathrm{~nm}, 400 \mathrm{~nm}$ and 600 nm and two negative dichroic signals centered at 300 nm and 465 nm .2 S shows Cotton effects of the opposite sign at the same wavelengths. The CD spectra of $\mathbf{2 R}$ and $\mathbf{2 S}$ in methanol are similar to those in KBr pellets except that the peaks at 265 nm are absent. The bands near 300 $\mathrm{nm}, 400 \mathrm{~nm}, 450 \mathrm{~nm}$ and 600 nm generally correspond to $\pi-\pi *$ transitions of benzene ring, $\pi-\pi *$ transitions and $n-\pi^{*}$. ransitions originating from the azomethine chromophore and $d-d$ transitions, respectively. ${ }^{16}$

The UV spectrum of 1S recorded in methanol solution shows three bands at $275 \mathrm{~nm}, 310 \mathrm{~nm}$ with shoulders on their low-energy sides and a broad peak near 400 nm , which are in accordance with the CD spectra. The UV spectrum of $\mathbf{2 R}$ exhibits three bands near $280 \mathrm{~nm}, 380 \mathrm{~nm}$ and 680 nm (Figure S2).

## Magnetic Properties

The magnetic properties of compounds $\mathbf{1 R} \mathbf{1 S}, \mathbf{2 R}$ and $\mathbf{2 S}$ were investigated between 2 K and 300 K using Quantum Design SQUID magnetometer MPMS XL-7. Both enantiomorphous 1R and $\mathbf{1 S}$ have similar magnetic behaviors, suggesting that the chirality of $\mathbf{1 R}$ and $\mathbf{1 S}$ have very little influence on the magnetism of them (Figure 4a,b). There exhibits a decrease of the magnetic moment value as the temperature drops,
indicating the presence of dominant antiferromagnetic interaction between the manganese spins (Figure 4c). Because the two $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ clusters in the asymmetric unit have only small difference in the terminal ligands (the $\mathrm{N}_{3}{ }^{-}$and disordered $\mathrm{N}_{3} / \mathrm{Br}^{-}$), they were treated using the same $\mathrm{Mn}_{4}$ model (Scheme 2a). The four units are one $\left\{\mathrm{Mn}^{\mathrm{II}} \mathrm{O}_{5} \mathrm{~N}\right\}$, one $\left\{\mathrm{Mn}^{\mathrm{III}} \mathrm{O}_{5} \mathrm{~N}\right\}$ and two $\left\{\mathrm{Mn}^{\mathrm{III}} \mathrm{O}_{4} \mathrm{NBr}\right\}$ respectively, corresponding to $\mathrm{S}_{4}=5 / 2$ $\left(\mathrm{Mn}^{\mathrm{II}}\right), \mathrm{S}_{1}=\mathrm{S}_{2}=\mathrm{S}_{3}=2\left(\mathrm{Mn}^{\text {III }}\right)$. The susceptibility was simulated on the basis of their molecular structures in the frame of an isotropic Heisenberg model, similar to that used in the analogous $\mathrm{Mn}_{4}$ clusters reported by Powell et al. ${ }^{12}$ As for the six non-equivalent couplings, similar bridges between the manganese ions were considered to be identical in the fitting and bridging modes. The best-fit parameters obtained within the isotropic model are $J_{1}=-2.9 \mathrm{~cm}^{-1}, J_{2}=-14.0 \mathrm{~cm}^{-1}, J_{3}=-12.0 \mathrm{~cm}^{-1}, g_{\mathrm{Mn}(\mathrm{II})}=g_{\mathrm{Mn}(\mathrm{III})}=2.0$ (fixed). The crucial factor for improving the overall fit is inclusive of the zero-field terms for $\mathrm{Mn}(\mathrm{III})$ centers using the modified Spin Hamiltonian as $\hat{H}_{a}=-J_{1}\left(S_{1} \cdot S_{4}+S_{2} \cdot S_{4}+S_{3} \cdot S_{4}\right)-J_{2}\left(S_{1} \cdot S_{2}+S_{2} \cdot S_{3}\right)-J_{3}\left(S_{1} \cdot S_{3}\right)+\sum S_{\mathrm{i}} \cdot D_{\mathrm{i}}: S_{\mathrm{i}}+\mu_{\mathrm{B}} \sum S_{\mathrm{i}} \cdot B_{\mathrm{a}} \cdot g_{\mathrm{i}}$. The best-fit parameters are $J_{1}=-3.3 \mathrm{~cm}^{-1}, J_{2}=-12.7 \mathrm{~cm}^{-1}, J_{3}=-14.8 \mathrm{~cm}^{-1}, g_{\mathrm{Mn}(\mathrm{II})}=g_{\mathrm{Mn}(\mathrm{III})}=2.0$ (fixed) and $D_{1, \mathrm{Mn}(\text { III })}=D_{2, \mathrm{Mn}(\text { III })}=D_{3, \mathrm{Mn}(\text { III })}=+5.0 \mathrm{~cm}^{-1}$ (Figure 4c). It should be noted that the $J$ values obtained from both computing models are comparable though the fitting results are not perfectly well due to the presence of two sets of $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ units within the asymmetric unit. The small difference in the bond angles and distances among manganese centers have been ignored and simplified to one set of parameters. All the $J$ values are negative in both simulated models, suggesting that anti-ferromagnetic coupling occurs between the adjacent Mn centers and both compounds 1R and 1S possess $S_{T}=1 / 2$ ground state. Though there is an azide bridging in the end-on fashion between Mn 1 and Mn 3 , it is too weak to influence the interactions compared with the $\mu_{3}-\mathrm{O}$ bridge. The $D$ parameter in the best fit is positive and the attempts to fit the susceptibility data with negatives values of $D$ failed.

The members of triangular $\left[\mathrm{Mn}^{\mathrm{III}}{ }_{3} \mathrm{O}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{6} \mathrm{~L}_{3}\right]^{+}$complexes containing the $\left[\mathrm{Mn}_{3}\left(\mu_{3}-\mathrm{O}\right)\right]$ core are nonnegligible as a part of SMMs family. ${ }^{4}$ Milios, Brechin and co-workers discovered for the manganses salicylaldoxime complexes that the $\mathrm{Mn}-\mathrm{N}-\mathrm{O}-\mathrm{Mn}$ torsion angles $(\alpha)$ on the $\left[\mathrm{Mn}_{3}\left(\mu_{3}-\mathrm{O}\right)\right]$ trinuclear moieties are highly correlative to the ground-state spin values of the complexes and accordingly, the sign of the magnetic interaction between neighboring Mn atoms. ${ }^{4 \mathrm{a}, \mathrm{f}}$ Nevertheless, no such torsion angles can be found
in Schiff base complexes $\mathbf{1 R}$ and $\mathbf{1 S}$. Another distinct difference between the SMMs with $\left[\mathrm{Mn}_{3}\left(\mu_{3}-\mathrm{O}\right)\right]$ cored and $\mathbf{1 R} / \mathbf{1 S}$ is the orientation of the Jahn-Teller axes of the manganese atoms. The axes on the SMMs are approximately parallel to each other and arrayed perpendicular to the $\left[\mathrm{Mn}_{3}\left(\mu_{3}-\mathrm{O}\right)\right]$ planes while in $\mathbf{1 R} / \mathbf{1 S}$, the Jahn-Teller axes are aligned on the $\left[\mathrm{Mn}_{3}\left(\mu_{3}-\mathrm{O}\right)\right]$ planes. $D>0$ is in agreement with the absence of SMM properties.

Both enantiomorphous 2R and 2S have very similar magnetic behaviors, suggesting that the chirality has almost no influence on the magnetism of $\mathbf{2 R}$ and $\mathbf{2 S}$ (Figure 5a,b). The value of $\mu_{\text {eff }}$ is $4.3 \mu_{\mathrm{B}}$ per $\mathrm{Cu}_{6}$ unit for $\mathbf{2 R}$ at room temperature, which is in agreement with the expected sum of six non-interacting $\mathrm{Cu}^{2+}(S=$ ${ }^{1} / 2$ ) cations ( $4.2 \mu_{\mathrm{B}}$ for $g=2.0$ ). Upon cooling the sample, the $\mu_{\text {eff }}$ decreases to a minimum value at 20 K and gradually turns up, indicative of the presence of dominant antiferromagnetic and weak ferromagnetic interactions between the copper spins within Cu 6 core. In order to reduce the number of parameters and avoid overparameterization, ${ }^{15,17}$ we supposed that two exchange parameters $J_{1}$ (via three short $\mathrm{Cu}-\mathrm{O}$ bonds) and $J_{2}$ (via two short $\mathrm{Cu}-\mathrm{O}$ bonds) are associated with the intracubane $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ exchanges, another two exchange parameters $\left(J_{3}\right.$ and $\left.J_{4}\right)$ are associated with the cubane $-\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2} \mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ and $\mathrm{Cu}-\mathrm{N}_{\text {azide }}-\mathrm{Cu}$ exchanges, respectively, and the fifth exchange parameter $\left(J_{5}\right)$ is associated with the intra- $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2} \mathrm{Cu}$ $\mathrm{N}_{\text {azide }}-\mathrm{Cu}$ exchange (Scheme 2b). A full analysis of the magnetic exchange interactions has been performed using the full-matrix diagonalization program MAGPACK ${ }^{18}$ with the Hamiltonian $\hat{\boldsymbol{H}}=-2 J_{1}\left(\boldsymbol{S}_{\mathbf{1}} \cdot \boldsymbol{S}_{\mathbf{2}}+\boldsymbol{S}_{\mathbf{2}} \cdot \boldsymbol{S}_{4}+\right.$ $\left.\boldsymbol{S}_{1} \cdot \boldsymbol{S}_{\mathbf{3}}+\boldsymbol{S}_{\mathbf{3}} \cdot \boldsymbol{S}_{4}\right)-2 J_{2} \boldsymbol{S}_{\mathbf{2}} \cdot \boldsymbol{S}_{\mathbf{3}}-2 J_{3} \boldsymbol{S}_{\mathbf{3}} \cdot \boldsymbol{S}_{\mathbf{5}}-2 J_{4} \boldsymbol{S}_{\mathbf{4}} \cdot \boldsymbol{S}_{\mathbf{5}}-2 J_{5} \boldsymbol{S}_{\mathbf{5}} \cdot \boldsymbol{S}_{\mathbf{6}}$. The best-fitted values are $g=2.12, J_{1}=-75.0 \mathrm{~cm}^{-1}$, $J_{2}=+1.8 \mathrm{~cm}^{-1}, J_{3}=-67.8 \mathrm{~cm}^{-1}, J_{4}=5.8 \mathrm{~cm}^{-1}$ and $J_{5}=8.2 \mathrm{~cm}^{-1}$ (Figure 5c). This analysis leads to the conclusion that both compounds $\mathbf{2 R}$ and $\mathbf{2 S}$ possess $S_{T}=1$ ground state, which is in the agreement with the isothermal magnetization saturation value (Figure 5b).

The irregular cubane $\mathrm{Cu}_{4} \mathrm{O}_{4}$ cores within compounds 2 R and 2 S are characteristic of five short (3.1886(15)- 3.3274(14) $\AA$ for 2R and 3.1667(12)-3.3859(11) $\AA$ for 2S) and one long $\mathrm{Cu}{ }^{\cdots} \mathrm{Cu}$ distances (3.897 $\AA$ for $\mathbf{2 R}$ and $3.9002 \AA$ for $\mathbf{2 S}$ ), which is different from those reported types of cubane structures such as the $2+4$ class, $4+2$ class and $6+0$ class based on the length of the $\mathrm{Cu} \cdots \mathrm{Cu}$ separation as a classification criterion proposed by Javier Tercero et al. ${ }^{19}$ From a $\left[\mathrm{Cu}_{4}(\mu-\mathrm{OMe})_{4}\left(\mathrm{NH}_{3}\right)_{8}\right]^{4+}$ model
corresponding to those $4+2$ cubane compounds, the calculated $J$ coupling constant corresponding to the exchange pathway with two short $\mathrm{Cu}-\mathrm{O}$ bond distances may result in either ferromagnetic or antiferromagnetic interactions depending on the value of the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle $(\beta)$. An increase in the $\mathrm{Cu}-\mathrm{O}-$ Cu angle finally leads to antiferromagnetic coupling for $\beta \approx 104^{\circ}$. For $\mathbf{2 R}$, as the $\beta$ is significantly larger than $104^{\circ}$, antiferromagnetic interaction is predicted. ${ }^{20}$ Compared with the result of Jäger and Klemm ( $\beta=$ $\left.99.3-102.9^{\circ}, J=-50 \mathrm{~cm}^{-1}\right),{ }^{21}$ which is in agreement with the above experimental data fitting results of $J_{1}=-$ $75.0 \mathrm{~cm}^{-1}$. The Cu3-O-Cu5 exchange pathway also transmits a moderate antiferromagnetic intereaction with the exchange parameter of $J_{3}=-67.8 \mathrm{~cm}^{-1}$. The exchange parameter of $J_{4}=5.8 \mathrm{~cm}^{-1}$ for the asymmetric $\mathrm{Cu} 4-\mathrm{N}_{\mathrm{azide}}-\mathrm{Cu} 5$ exchange pathway corresponds to weak ferromagnetic coupling due to the perpendicular orientation of the magnetic orbital. The symmetric $\mathrm{Cu5}$-( $\mu_{1,1}$-azido $)_{2}-\mathrm{Cu} 6$ exchange pathway with the $\mathrm{Cu}-$ $\mathrm{N}_{\text {azido }}-\mathrm{Cu}$ angles $(\theta)$ of $101.4(4)^{\circ}$ and $103.2(4)^{\circ}$, which are less than $108.8^{\circ}$, is predicted to be ferromagnetic. ${ }^{22 a}$ Eliseo Ruiz and coworkers discussed the relation between the $J$ values and the $\mathrm{Cu}-\mathrm{N}-\mathrm{Cu}$ angle $(\theta)$ as well as the out-of-plane deviation of the azido group $(\tau)$ for the azido-bridged compounds. One double end-on azido-bridged complex with $\theta=104.6^{\circ}, \tau=16.6^{\circ}$ and calculated $J=+5 \mathrm{~cm}^{-1}$ has been reported, ${ }^{22 \mathrm{~b}}$ which is similar to 2R with $\theta=101.4^{\circ} / 103.2(4)^{\circ}, \tau=10.6^{\circ} / 17.9^{\circ}$ and $J_{5}=+8.2 \mathrm{~cm}^{-1}$.

## Conclusion

We have prepared and characterized four enantiomerically pure chiral polynuclear transition metal complexes with Schiff base ligands $R$ - and $S-\mathrm{H}_{2} \mathbf{L} . \mathbf{1 R}$ and $\mathbf{1 S}$ are tetranuclear clusters with three $\mathrm{Mn}($ III $)$ ions and one $\mathrm{Mn}(\mathrm{II})$ ion combined via $\mu_{3}-\mathrm{O}$ and $R-/ S-\mathrm{H}_{2} \mathbf{L}$ ligands. Enantiomeric $2 \mathbf{S}$ and $\mathbf{2 R}$ are cappedcubane $\mathrm{Cu}_{6} \mathrm{O}_{5} \mathrm{~N}_{3}$ clusters with the phenoxo group and $\mathrm{N}_{3}{ }^{-}$as bridges to link the "cubane" and "cap". The enantiomeric nature of $\mathbf{1 R}, \mathbf{1 S}, \mathbf{2 R}$ and $\mathbf{2 S}$ was confirmed via CD spectroscopy. Magnetic investigation reveals that antiferromagnetic interactions occur between adjacent manganese ions in $\mathbf{1 R}$ and $\mathbf{1 S}$. An overall antiferromagnetic coupling was found for $\mathbf{2 R}$ and $\mathbf{2 S}$ via competition of the slightly dominating intra-cubane antiferromagnetic interaction and the cubane $-\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$ antiferromagnetic exchange over the intra- $\mathrm{Cu}_{2}\left(\mathrm{~N}_{3}\right)_{2}$
ferromagnetic interaction through the double $\mu_{1,1}-\mathrm{N}_{3}$ bridges. Our results suggest a promising strategy to synthesize molecular magnets with chirality towards the MChD effect.

Scheme 2 (a) Scheme of the magnetic interactions in $\mathbf{1 R}$ according to spin Hamiltonian (eq. 1). (azide is showed instead of $75 \%$ azide and $25 \%$ bromide ions disorder). (b) Scheme of the magnetic interactions among copper centers in $\mathbf{2 R}$.

Figure 1 ORTEP drawings of the two similar $\mathrm{NaMn}_{4}$ clusters (a) and the $\mathrm{NaMn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ cores (b) in the asymmetric unit of $\mathbf{1 R}$ (left) and 1S (right) with thermal ellipsoids at $50 \%$ probability (Br ions are showed instead of $75 \%$ azide and $25 \%$ bromide ions disorder between two $\mathrm{Mn}^{\text {III }}$ ions as a bridge in the clusters of Mn 1 .).

Figure 2 ORTEP drawings of the $\mathrm{Cu}_{6}$ clusters (a) and the $\mathrm{Cu}^{\mathrm{II}}{ }_{6}$ cores (b) in the asymmetric unit of $\mathbf{2 R}$ (left) and $\mathbf{2 S}$ (right) with ellipsoids at $50 \%$ probability. The open lines represent the elongated $\mathrm{Cu}-\mathrm{O}$ bonds in the cubane unit, while the dashed lines represent the eye-guides of the cubane sketch.

Figure 3 Room-temperature CD spectra of $\mathbf{1 R}$, $\mathbf{1 S}$ and $\mathbf{2 R}, \mathbf{2 S}$ in KBr pellets.

Figure 4 (a) Plots of $\mu_{\text {eff }}$ as a function of $T$ for $\mathbf{1 R}$ and 1S. (b) Magnetization at $2 \mathrm{~K} v s$. applied field for 1R and 1S. (c) Temperature dependence of the effective magnetic moment for $\mathbf{1 R}$ (calculated from magnetization at $B=$ 0.05 T ), with the low-temperature region expanded in the inset. (d) Field dependence of magnetization for $\mathbf{1 R}$ at $T=2 \mathrm{~K}$. Empty circles - experimental data, full lines - calculated data with the spin Hamiltonian and parameters in the text.

Figure 5 (a) Plots of $\mu_{\text {eff }}$ as a function of $T$ for $\mathbf{2 R}$ and $\mathbf{2 S}$. (b) Magnetization at $2 \mathrm{~K} v s$. applied field for $\mathbf{2 R}$ and $\mathbf{2 S}$. (c) Temperature dependence of the effective magnetic moment for $\mathbf{2 R}$ (calculated from magnetization at $B=$ 0.05 T). Empty circles - experimental data, full lines - calculated data with the spin Hamiltonian and parameters in the text.

## Synopsis for Table of Contents

Two enantiomeric Schiff base ligands $R-/ S-\mathrm{H}_{2} \mathbf{L}$ in situ generated from $o$-vanillin and $R$ - or $S-2-$ phenylglycinol were applied to assemble chiral multinuclear magnetic clusters. Two new enantiomorphous $\mathrm{Mn}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{III}}{ }_{3}$ clusters and two new enantiomorphous $\mathrm{Cu}^{\mathrm{II}}{ }_{6}$ clusters have been synthesized and characterized by X-ray crystallography, CD spectroscopy and magnetism.
