The third-order NLO measurements of 1–5

The solutions of **1** (6.0×10^{-5} M), **2** (6.0×10^{-5} M), **3** (6.0×10^{-5} M), **4** (6.0×10^{-5} M), and **5** (6.0×10^{-5} M) in DMF were placed in a 1.5 mm quartz cuvette for the third-order NLO measurements. These five compounds were stable toward air and laser light under experimental conditions. As a reference, the optical nonlinearity of the standard sample CS₂ was also observed. The third-order NLO properties were measured using femtosecond DFWM technique with a Ti:Sapphire laser (Spectra-physics Spitfire Amplifier). The pulse width was determined to be 80 fs on a SSA25 autocorrelator. The operating wavelength was centered at 800 nm. The repetition rate of the pulses was 1 kHz. During the measurement the laser was very stable (rms < 0.1%). The input beam was split into two beams k_1 and k_2 with nearly equal energy by use of a beam splitter (BS) and then focused on a spot of the sample. The beam k_2 passed through a delay line derived by a stepping motor in order that the optical path length difference between the k_2 and k_1 beams could be adjusted during the measurement. The angle between the beams k_1 and k_2 were about 5°. When k_1 and k_2 were overlapped spatially in the sample, the generated signal beam k_3 passed through an aperture, recorded by a photodiode and then analyzed by a lock-in amplifier and computer.

Details of the equations used in calculations of third-order NLO properties

The third-order nonlinear optical susceptibility $\chi^{(3)}$ is measured *via* a comparison with that of a reference sample CS₂, calculated from the DFWM signal (I), the linear refractive index (n), the sample thickness (L) and absorption correction factor using eq. 1:^[1]

$$\chi_s^{(3)} = \left(\frac{I_s}{I_r} \right)^{1/2} \cdot \frac{L_r}{L_s} \cdot \left(\frac{n_s}{n_r} \right)^2 \cdot \frac{\alpha \cdot L \cdot \exp(\alpha L / 2)}{1 - \exp(-\alpha L)} \cdot \chi_r^{(3)} \quad (1)$$

where the subscripts “s” and “r” represent the parameters for the sample and CS₂. And α is the linear absorption coefficient. The last fraction comes from the sample absorption and equals to 1 while the sample has no absorption around the employed laser wavelength. The values of $\chi_r^{(3)}$ and n_r for CS₂ are 6.7×10^{-14} esu and 1.632, respectively.^[2]

The third-order nonlinear refractive index n_2 in isotropic media is estimated through eq. 2:^[3]

$$n_2(\text{esu}) = \frac{12\pi\chi^{(3)}}{n^2} \quad (2)$$

where n is the linear refractive index of the solution.

The second-order hyperpolarizability γ of a molecule in isotropic media is related to the solution $\chi^{(3)}$ by Equation (3):^[4]

$$\gamma = \frac{\chi^{(3)}}{Nf^4} \quad (3)$$

where N is the number density of the solute per milliliter, and f^4 is the local field correction factor which is $[(n^2 + 2)/3]^4$ (n is the linear refractive index of solution).
