## 18 2. Materials and methods

19

### 20 2.1. Materials and fish exposure

21 Eight PhACs were selected for this study based on their high usage rates and  
22 frequent occurrence in surface water in China.<sup>1,2</sup> The standards of roxithromycin  
23 (ROX), erythromycin (ERY), ketoconazole (KCZ), ibuprofen (IBU), diclofenac (DIC),  
24 propranolol (PRO), carbamazepine (CBZ) and 17 $\alpha$ -ethinylestradiol (EE2) were  
25 purchased from the laboratory of Dr. Ehrenstorfer (Augsburg, Germany).  
26 Erythromycin-13C,d3, carbamazepine-d10, ibuprofen-d3 and estrone-d4 were  
27 obtained from Sigma-Aldrich (Flanders, New Jersey, USA). Crucian carp were  
28 purchased from the Nanjing Institute of Fishery Science (Nanjing, China).

29 Crucian carp (*Carassius auratus*) is an important economic species widely  
30 distributed in the freshwaters of China. It has been demonstrated to be a very sensitive  
31 species to study the toxic effects of pollutants on aquatic organisms.<sup>3</sup> In the laboratory,  
32 the fish were fed every day with commercial fish food (6% of body weight/day).  
33 According to OECD guideline 305,<sup>4</sup> the exposure water's quality was checked daily  
34 and maintained at conditions suitable for crucian carp (Water temperatures  $9 \pm 1$  °C;  
35 pH  $7.4 \pm 0.3$ ; DO  $7.5 \pm 0.5$  and CaCO<sub>3</sub>  $110.5 \pm 3.5$  mg L<sup>-1</sup> ). Feces and uneaten food  
36 were removed every day by suction. Natural light conditions were used throughout  
37 the experiment.

38

### 39 2.2. Biomarker assays, HSI, EROD and GST

40 Hepatosomatic index (HSI) was calculated as follow:  $HSI = (W_L/W_B) \times 100$ ,  
41 where  $W_L$  is the weight of the liver in grams and  $W_B$  is the body weight in grams.  
42 Liver samples were homogenized in nine volumes of cold buffer (0.15 M KCl, 0.1 M  
43 Tris-HCl, pH 7.4) and centrifuged for 25 min (10,000 $\times$ g) at 4 °C. The supernatants  
44 were used as the extract for enzymatic activity determination. The use of S9 fractions  
45 is convenient and relatively cheap compared with using cytosol and microsomes. The

46 EROD activity was determined at 572 nm using a microplate reader. Specifically, 10  
47  $\mu\text{L}$  of supernatant, 140  $\mu\text{L}$  buffer (0.1 M Tris, 0.15 M KCl, pH 8.0) and 10  $\mu\text{L}$  of 2  
48  $\mu\text{M}$  7-ethoxyresorufin were added to a 96-well microplate. The reaction was then  
49 initiated at 25 °C for 30 min by adding 40  $\mu\text{L}$  of 2.1  $\text{mg mL}^{-1}$  NADPH. NADPH was  
50 replaced by  $\text{H}_2\text{O}$  in the control wells. The molar extinction coefficient of the resorufin  
51 was 73  $\text{L mmol}^{-1} \text{cm}^{-1}$ . The EROD activity was expressed as  $\text{pmol mg pro}^{-1} \text{min}^{-1}$ .  
52 GST activity was determined at 340 nm by adapting to a microplate reader, using 30  
53  $\mu\text{L}$  of homogenate and 150  $\mu\text{L}$  of the reaction solution (100  $\mu\text{L}$  of 0.1 mM potassium  
54 phosphate, 10  $\mu\text{L}$  of 1.0 mM 1-chloro-2,4-dinitrobenzene, 10  $\mu\text{L}$  of 1.0 mM GSH and  
55 880  $\mu\text{L}$   $\text{H}_2\text{O}$ ) in microplates, and this activity was measured for 3 min. GST activity  
56 was expressed as  $\text{nmol mg pro}^{-1} \text{min}^{-1}$ .

57

### 58 **2.3. Sample extraction**

59 Tissue samples were extracted by pressurized liquid extraction (PLE) using a  
60 Dionex ASE 350 system (Thermo Fisher, Germering, Germany). Each tissue sample  
61 (1 g wet weight (ww) for muscle, gill and brain and 0.5 g ww for liver) was  
62 thoroughly mixed with hydromatrix and the mixture was put into a 22-mL stainless  
63 steel extraction cell containing a glass-fiber filter (27-mm diameter, type D28, Dionex)  
64 in the cell inlet and outlet. The extracting solvent was 100% methanol, and the  
65 operating conditions were as follows: extraction temperature, 70 °C; extraction  
66 pressure, 1500 psi; preheating period, 5 min; static extraction, 5 min; nitrogen purge,  
67 180 s; and three static cycles.

68 Each PLE extract was concentrated to approximately 1 mL in a Büchi R200  
69 (Labortechnik, Flawail, Switzerland) rotary evaporator set at 45 °C and 19600 Pa in a  
70 50-mL round-bottomed flask. Then, the extract was transferred to a 15-mL conical  
71 tube and the round-bottomed flask was rinsed twice with 0.5 mL of methanol and  
72 evaporated to dryness using a multi-sample N-EVAP with a nitrogen stream and  
73 water bath at 50 °C. After solvent evaporation the extract was redissolved in 1 mL of  
74 acetonitrile, which has a low solubility for lipids. A freezing-lipid technique was  
75 applied, by means of redissolving the extract in acetonitrile and storing the extract in  
76 the freezer at -80 °C for 4 h. Most of the lipids precipitated out of solution and the  
77 extract was immediately centrifuged at 0 °C and 12000×g for 15 min. The  
78 supernatants were decanted into a chromatography bottle and reconstituted with 1 mL  
79 of acetonitrile, and 50 µL of the 1 mg L<sup>-1</sup> mixture containing the internal standards  
80 were added.

81 Water samples (500 mL) were passed through Oasis HLB 6cc SPE cartridges  
82 (500 mg, Waters, USA). The cartridges were preconditioned with 6 mL of methanol  
83 and 6 mL of water. The samples were eluted from the cartridges using 2 × 3 mL of  
84 methanol. The extracts were evaporated to dryness under a stream of nitrogen,  
85 reconstituted with 1 mL acetonitrile, and analyzed by UPLC/MS/MS.

86

#### 87 **2.4. Instrumental analysis**

88 Liquid chromatography was performed on an Agilent 1290 ultra-high  
89 performance liquid chromatography (UPLC) system (Agilent Technologies)  
90 consisting of a binary pump, a micro-vacuum degasser, an autosampler equipped with

91 a 1200 bar injection valve and a column oven (set to 30 °C). Analytes were separated  
92 on an Eclipse Plus C18 (150 mm × 4.6 mm, 5 μm, Agilent Technologies) column  
93 preceded by a C18 guard column at a flow rate of 0.3 mL min<sup>-1</sup>. The injection volume  
94 was 5 μL. A binary gradient consisting of 0.1% (v/v) formic acid/0.02 mM  
95 ammonium acetate in water and 100% acetonitrile was employed to achieve  
96 separation as shown in Table S1. Detection was performed with an Agilent 6460 triple  
97 quadrupole mass spectrometer equipped with an electrospray ionization source (ESI).  
98 The ROX, ERY, KCZ, PRO and CBZ in the tissue and water samples were analyzed  
99 in the positive mode, whereas the DIC, IBU and EE2 were analyzed in the negative  
100 mode. The capillary voltage was held at 4 KV and the gas flow was set at 6 L min<sup>-1</sup>.  
101 The pressure of the nebulizing gas was 35 psi. The sheath gas temperature was held at  
102 350 °C and the gas flow was 9 L min<sup>-1</sup>. The triple quadrupole was used in the  
103 multiple-reaction monitoring (MRM) mode to identify and quantify the compounds.  
104 The collision energy, the fragmentor voltage, the precursor and the production ions  
105 optimized by the direct infusion of standard compounds are presented in Table S2.

106 Whole analytical procedures were monitored using strict quality assurance and  
107 control measures. The method sensitivity was calculated by determining the method  
108 detection limits (MDL), the limit of detection (LOD) and the limit of quantitation  
109 (LOQ) for the target compounds. The MDLs of the target compounds calculated using  
110 standard solutions were 0.05–0.12 ng L<sup>-1</sup>. For the water samples, the LODs and  
111 LOQs of the target compounds were 0.07–0.15 and 0.27–0.65 ng L<sup>-1</sup>, respectively.  
112 Similarly, the LODs and LOQs of the target compounds corresponding to fish tissues

113 were 0.1–0.3 and 0.4–1.2 ng g<sup>-1</sup>, respectively. Satisfactory recoveries were obtained  
114 for the target compounds in the range of 83.7–105.2% for the water samples and  
115 62.4–83.6% for the fish samples.

116

## 117 **2.5. Environmental implications**

118 An environmental risk assessment of individual pharmaceuticals was performed  
119 based on chronic data and acute data according to the EMA guideline and REACH  
120 guideline<sup>5</sup>, respectively. Typically, the risk quotient (RQ) of individual  
121 pharmaceuticals is calculated via their measured environmental concentration (MEC)  
122 divided by the predicted no-effect concentration (PNEC), as shown in Equation (1):

$$123 \text{ RQ} = \frac{\text{MEC}}{\text{PNEC}} \quad (1)$$

124 According to the REACH guidance document, to estimate a PNEC on the basis of  
125 toxicity data, when only the short-term/acute toxicity data EC<sub>50</sub> or LC<sub>50</sub> are  
126 available, the calculation of PNEC is obtained from the EC<sub>50</sub> or LC<sub>50</sub> divided by an  
127 assessment factor (AF) of 1000. Once the long-term/chronic NOEC values for one,  
128 two or three trophic levels are available, an AF of 100, 50 or 10 is used.<sup>5</sup> In this study,  
129 an AF of 1000, 100 or 10 was used in relation to the toxicity of PhACs. In this study,  
130 the acute or chronic toxicity data of the detected PhACs on non-target organisms were  
131 collected from the literature and are shown in Table S3.

132 The environmental risk assessment of pharmaceutical mixtures was evaluated by  
133 the approach recently proposed by Backhaus and Faust. The approach for calculating  
134 the mixture RQ is outlined by Equation (2): the calculation of  $\Sigma \text{RQ}_{\text{MEC}/\text{PNEC}}$ , based on

135 the sum of MEC/PNEC values. The toxicity data EC50, LC50 or NOEC are  
 136 represented by EC50 in Equations (2).

$$\begin{aligned}
 137 \quad \Sigma RQ_{MEC/PNEC} &= \sum_{i=1}^n \frac{MEC_i}{PNEC_i} \\
 138 \quad &= \sum_{i=1}^n \frac{MEC_i}{\min (EC50_{aglse}, EC50_{daphnids}, EC50_{fish})_i \times (1/AF_i)} \\
 139 \quad &(2)
 \end{aligned}$$

140 The biomarker response data for each point were standardized according to  
 141 Eq.(3):

$$142 \quad Y_i = (X_i - m) / s \quad (3)$$

143 where  $Y_i$  is the standardized value of the biomarker,  $X_i$  is the mean value of a  
 144 biomarker at each point, and  $m$  and  $s$  are the mean value and the standard deviation of  
 145 a biomarker with all of the sampling points considered, respectively.

146 Using standardized data,  $Z_i$  was then calculated as  $Z_i = Y_i$  or  $Z_i = -Y_i$  in the case  
 147 of a biomarker responding to contamination by induction or inhibition, respectively.  
 148 The minimum value ( $\min Z_i$ ) for each biomarker at all of the points was calculated  
 149 from the standardized response value. The score of each biomarker response ( $S_i$ ) was  
 150 calculated as:

$$151 \quad S_i = Z_i + |\min Z_i| \quad (4)$$

152 Finally, to obtain an integrated multi-biomarker response, the EIBR value was  
 153 calculated as the sum of the weighting of the biomarker and the biomarker score as  
 154 follows:

$$155 \text{ EIBR} = \frac{\sum_i^n Si}{\sum_i^n Wi} \times \frac{\sum_i^n Wi}{\sum_i^n Si} \quad (5)$$

156 where  $W_i$  is the weighting of each biomarker  $i$ , and molecular (EROD and GST) and  
 157 physiological (HSI) biomarkers are weighted as 1 and 3, respectively, because it is  
 158 assumed that an alteration at the physiological level would have a greater impact on  
 159 the health of the organisms than changes at the molecular level.

160 **Table S1.**

Time (min)	Composition of the mobile phase (%)	
Positive mode	Eluent A1 (0.1% (v/v) Formic acid)	Eluent B1 (Acetonitrile)
0	80	20
0.5	80	20
4	10	90
5	10	90
5.5	80	20
Negative mode	Eluent A2 (0.02 Mm Ammonium acetate)	Eluent B2 (Acetonitrile)
0	80	20
0.5	80	20
6	5	95
6.5	80	20
