## High pressure cell temperature calibration

Temperature of the high pressure cell was monitored using a thermocouple (Watlow Electric Manufacturing Company; max. temperature: 1700 °C, accuracy:  $\pm 2$  °C) attached to the external surface of the high pressure cell. Because of the difference between the internal temperature and the external temperature, an experiment was conducted to estimate the internal temperature based on the external temperature. A thermocouple (Omega Engineering; max. temperature: 750 °C, accuracy:  $\pm 2$  °C) was inserted into the high pressure cell through the venting hole (Fig. S1), and the internal temperature was compared with the external temperature measured from the surface of the high pressure cell. The external temperature was increased up to 300 °C, and then deionized water was injected into the cell to completely submerge the thermocouple inserted

inside the cell in water. The pressure was 155 atm at the external temperature of 300 °C without addition of CO<sub>2</sub>. In this experiment, the cell was not pressurized with CO<sub>2</sub> for the sake of safety. After the heat was turned off, both external and internal temperatures were monitored simultaneously while the temperatures decreased. The internal and external temperatures were monitored as the external temperature decreased from 300 °C to 60 °C, which corresponded to the internal temperature decrease from 402 °C to 73 °C (Fig. 2). At the external temperature interval between 60 °C and 300 °C, there was a strong linear correlation between external temperature ( $R^2 = 0.999$ ; n = 18), which showed higher internal temperature than external temperature. Therefore, internal temperatures in the following experiments were estimated based on the linear relationship and external temperatures measured using a thermocouple.

**Fig. S3.** Relationship between external temperature and internal temperature for the high pressure cell

**Fig. S4.** A: Picture of raw rock cores collected from Coso geothermal field. B: Picture of a cemented rock core (0.625" D and 2" L) with HIP tubing (1/16" OD) for hydraulic fracturing experiment. B: XMT image of a cemented rock core; A few days after cementing the rock core, additional cement layer covered the rock core to maximize the sealing under high confining pressure (204 atm).

Fig. S5. Schematic diagram for the hydraulic fracturing experimental setup.

Fig. S6. Photo showing the experimental setup for hydraulic fracturing.

**Fig. S7**. Volume changes of PAA solution reacted with  $CO_2$  as a function of temperature (58–402°C) and  $CO_2$  pressure (0–300 atm).  $CO_2$  pressure was increased from 110 to 300 atm, except for the experiment at 402°C (170–300 atm), where the initial pressure of PAA solution at 402°C was 150 atm before  $CO_2$  injection. The dashed lines indicate the boundary between PAA fluid and supercritical  $CO_2$  (after  $CO_2$  injection) or air/water vapor (before  $CO_2$  injection). The window is partially covered by some residual PAA. Compare these results with Figure S8 for DIW/CO<sub>2</sub>.

**Fig. S8.** The volume and rheology changes of deionized water after  $CO_2$  injection at 333 °C. The bottom half is deionized water and the top half is air or supercritical  $CO_2$ .

**Fig. S9.** Volume changes of recycled PAA solution (1 wt%) before and after  $CO_2$  injection. Some PAA was not dissolved back and may be the reason for the observed smaller volume expansion observed on the third recycle as compared to the first recycle.

**Fig. S10**. Viscosity of deionized water-CO<sub>2</sub> mixture as a function of CO2 pressure at 190 °C (shear rate 100 s<sup>-1</sup>)

**Fig. S11** Comparison of fluid viscosity as a function of  $CO_2$  pressure at 190°C and 100 s<sup>-1</sup> shear rate (left) and as a function of shear rate at 190°C and 130 atm (right). A1 and B1: 1% PAA solution; A2 and B2: 0.1% xanthan gum solution; A3 and B3: 1% SDS solution. It is important to note that the instrument P/T limits are far below the pressure and temperatures required for the aqueous PAA-  $CO_2$  fluid to transition to a hydrogel.

**Fig. S12.** XMT images of rock cores from Coso geothermal site, CA before and after hydraulic fracturing experiment using 1 wt.% PAA and CO2 (Coso 1-1 and 1-2), 1 wt.% SDS and CO2 (Coso 1-3), and distilled water and CO2 (Coso 1-4). No XMT image is available for Coso 1-1 before hydraulic fracturing experiment.

**Fig. S13.** Pictures of CO<sub>2</sub> leakage experiment at ~5 atm CO<sub>2</sub> pressure. CO<sub>2</sub> bubbling from the rock surface was observed from the rock cores Coso 1-1 and Coso 1-2 (photos A and B) after hydraulic fracturing experiment with 1 wt.% PAA and CO<sub>2</sub>. No evidence of fractures was observed for DIW and CO<sub>2</sub> or 1 wt% aqueous SDS and CO<sub>2</sub> (photos C and D).

Fig. S14. Pictures of the injection of KI solution (0.3 g/mL) into the rock cores at  $\sim$ 7 atm N<sub>2</sub> after the hydraulic fracturing experiment with 1 wt.% PAA and CO<sub>2</sub>. The seepage of KI solution occurred through the fractured rock surface.

Fig. S15. Time-series of the seepage of the KI solution injected into the rock core (Coso 1-2) at  $\sim$ 7 atm N<sub>2</sub> pressure. The seepage of KI solution occurred on the upper left side of the rock surface within the red mark in 15 seconds, and then the seepage of KI solution occurred along a line within the red mark, which is presumed to be micro-fractures.

## Before Kl injection After Kl injection Image: Constraint of the sector of the sector

**Fig. S16.** XMT images of a horizontal slice of the fractured rock core (Coso 1-2) before and after the injection of KI solution (0.3 g/mL) at 7 atm  $N_2$  pressure. After the injection of KI solution, the cement sealing remaining on the outside surface of the rock core became brighter because of the seepage of KI solution.

**Fig. S17.** XMT image of a volume spanning 20 horizontal XMT slices on the fractured rock core (Coso 1-2) showing the presence of a local fracture created at 4 atm differential pressure. It is important to note, that although the fracture seems not to connect the internal void volume of the rock with its external surface, microfractures smaller than the resolution limit of the instrument are present and allow fluid flow through the rock as evidenced by  $CO_2$  and KI flow experiments.
