

Appendix A1.

Method – Thermal Ionization Mass Spectrometry (TIMS)

Feldspar minerals and sulfides chosen for thermal ionization mass spectrometry (TIMS) analysis were in the form of coarse solid fragments prior to dissolution with the exception of USGS MASS-1, which was a powder. All TIMS analytical work was performed in the Boise State University Isotope Geology Laboratory (IGL). For the feldspar minerals, each individual sample was between ~0.003 and 0.01g. Prior to dissolution, any potential surface contamination was removed from the feldspar separates through a series of steps. First, 1 mL of 3.5 N HNO₃ was added to each sample, the sample capped and placed on a hot plate at 120 C for ~30 minutes. The HNO₃ was then removed with a pipette and each sample was rinsed three-times with milli-Q H₂O. 1 mL of 6M HCl was then added to each sample and again each sample was capped and placed on a hotplate set at 120 C. After ~30 minutes, the HCl was removed with a pipette and each feldspar separate was rinsed three-times with 0.5 mL milli-Q H₂O. Following the milli-Q H₂O rinse, a mixture of 1 mL concentrated (16M) HNO₃ and 3 mL concentrated (29M) HF was added to each sample. Each feldspar sample was then capped and placed on a hotplate set at ~150 C overnight. For the solid sulfide samples PB-1 and B41, 0.004 to 0.015 g chunks were dissolved in a mixture of 0.5 mL concentrated (16M) HNO₃ and 0.2 mL concentrated (16M) HCl mixture overnight on a hotplate set at ~150 C. Prior to dissolution, each sulfide solid was rinsed three-times with milli-Q H₂O and sonicated in milli-Q H₂O for 10 minutes to remove any surface contamination. For MASS-1, the sulfide powder, ~ 0.01 g of power was dissolved in a mixture of 3 mL concentrated (16M) HNO₃ and 1 mL concentrated (16M) HCl and fluxed on a hotplate at ~150 C overnight.

After one night fluxing on a hotplate at ~150 C, all samples were fully dissolved in their respective acid mixtures. Each sample beaker was then uncapped and placed back on a hotplate under a heat lamp until dry. Once dry, 1 mL of concentrated (16M) HCl was added to each sample. Capped samples were then sonicated for ~1 hour. An additional 4 mL of 6M HCl (feldspar samples and MASS-1) or 1 mL of 6M HCl (PB-1 and B41) was added to each sample, the beakers capped and each sample was again placed back on a hotplate set at ~120 C to flux overnight. After ~24 hours on a hotplate, all samples were fully dissolved in 6M HCl. Each sample beaker was uncapped and the samples dried down to salts on a hotplate.

Supplemental Files – Souders and Sylvester

Both feldspar and sulfide samples were and then converted to PbBr_4^{2-} by adding 1 mL 0.5M HBr to each sample and placing on the hot plate until dry. Prior to ion exchange chromatography, each sample was redissolved in 1 mL of 0.5M HBr. Lead was separated from each matrix using ion-exchange columns filled with 100 μL (resin volume) AG1-X8, 200-400 mesh, and HCl-based anion exchange chromatography procedures.

Lead was analyzed on the Isoprobe-T thermal ionization mass spectrometer. Lead was loaded on single Re filaments with 1 – 2 μL of a dilute silica gel – 0.1M H_3PO_4 emitter solution. Lead was measured in static mode, maintaining a 3V ^{208}Pb beam for 200 cycles, or, for very small amounts of lead, dynamically peak-switching all ion beams into the Daly detector. TIMS lead isotope ratio results for the feldspars and sulfide minerals adopted for this study are listed in Table A2.

Appendix A2. Sample Characterization/Description

Prior to analysis, small separates (≤ 1 mm in thickness and no greater than 5 mm in any surface direction) of all silicate glasses, feldspars and sulfides were mounted in 10 mm or 25 mm diameter epoxy resin mounts and once cured, ground down to a flat surface and polished using diamond abrasive to expose a cross-sectional surface of each material. Sulfides and silicates were placed in separate epoxy mounts and the sulfides were polished on polishing cloths specifically designated for sulfide minerals.

The Shap orthoclase has been used in several other investigations^{1,2} as a secondary standard due to its homogeneous lead isotope composition on the μm -scale of a laser ablation analysis³. The Fish Canyon Tuff (FCT) sanidine has been analyzed for trace element concentrations, including lead, by Bachmann et al.⁴. TIMS lead isotope ratio values for the FCT sanidine adopted for this study are those determined by Hemming and Rasbury⁵. The bulk compositions of all three feldspars are given in Table A3.

Three different synthetic sulfides were analyzed as part of this investigation. Bulk analyses of

the three sulfides are presented in Table A4. Surface images highlighting the differences in physical character of the 3 sulfides analyzed are presented in Figure A2.1.

Figure A2.1 (A) Back-scattered electron (BSE) and (B) Secondary electron (SE) images of the same surface area of sulfide glass, PB-1. 30 – 40 µm diameter laser ablation pits and line scans mark the surface of the sulfide. (C and D) BSE images of sulfide sinter B-41 taken at two different magnifications. The area within the box in C is image D. The subtle changes in the gray-scale best seen in image D most likely are the result of individual grains approaching their melting points. (E) BSE and (F) SE images of the same surface area of pressed powder pellet MASS-1. Individual grains of different compositions can be readily identified in the BSE image by the varying levels of brightness. All images were collected on the JXA JEOL-8900L superprobe at McGill University.

Appendix A3.

Ablation Rate Determination Procedures

Ablation rates were calculated by dividing the surface to depth distance (μm) of a laser ablation crater by the ablation time to produce the crater (seconds). Representative craters for each matrix were drilled under ablation conditions identical to those used for each experiment. In order to monitor changes in pit morphology during the laser ablation interval, representative craters were produced for 10 seconds, 30 seconds and 60 seconds of laser ablation (3 different craters/matrix/set of ablation conditions). Secondary electron (SE) images of each crater were taken using a FEI Quanta 400 environmental secondary electron microscope (SEM) with an accelerating voltage of 15 kV and a beam diameter of 3.14 μm .

The surface to depth distance was determined in a series of steps (Figure A3.1). First, a SE image of the crater was taken to identify major physical features on the floor and walls of the pit. The SEM stage was then tilted to a 35 degree angle and a second SE image of the same crater was taken, making sure the SEM working distance (~ 20 mm) remained constant. Once distinguishing morphological features on the floor and walls of the crater had been identified, the tilt on the SEM stage was adjusted until the near-side crater rim was in line with the intersection of the crater floor and far-side crater wall (Figure A3.2). The tilt angle of the SEM stage was recorded and a third SE image was taken. After the proper tilt angle of the SEM stage was determined, the distance between the near-side crater rim and the crater wall/crater floor intersection point was measured directly from the ‘in-line’ tilted SE crater image. The surface to depth distance was calculated using the formula:

$$h = w * \tan(90 - \theta)$$

where: h = surface to depth distance
 w = crater width measured from ‘in-line’ tilted image
 θ = tilt angle of the SEM stage for ‘in-line’ image

The apparent drill rates calculated are a function of how fast the laser is drilling down into a matrix over a given period of time and how much material is excavated from the crater within the same time interval. Our method also assumes both the sample surface and crater floor

Supplemental Files – Souders and Sylvester

intersect the crater walls at right angles and the surface pit width equals the pit width on the crater floor. Determining the crater depth from sample surface to crater floor is critical when calculating drill rates, yet this quantitative measurement is obscured by melt deposition along the crater rim extending above the sample surface, and the build-up of melt droplet piles on the crater floor. The crater depth calculation assumes each crater is a cylinder, with a top and bottom of equal diameter and straight sides. This method does not account for tapering of the crater walls. Although variations exist between matrices, the estimate of the error on our apparent drill rate calculations does not exceed 20% of the calculated ablation rate. For example, if a 2 μm tall rim is associated with each ablation pit, the crater depth would decrease up to 11 % and there would be up to an 11% decrease in calculated drill rates. If we assume an $\sim 8 \mu\text{m}$ high melt droplet pile on each crater floor, the crater depth would increase by up to 20 %. This translates to an $\sim 20 \%$ increase in the drill rates calculated. It is important to note when considering the potential errors on the apparent drill rate calculations that the difference in drill rates between the $\sim 30 \mu\text{m}$ diameter craters and the $\sim 69 \mu\text{m}$ diameter craters are still distinct.

Supplemental Files – Souders and Sylvester

Figure A3.1. Secondary electron (SE) crater images. (A) Initial SE image taken to aid in the identification of major morphological features inside the crater. (B) Distance measured on ‘in-line’ tilt image to determine crater width (w). (C) Thirty-five degree stage-tilt SE image. The near-side crater rim and the intersection of the crater floor and far-side crater wall are marked with stars. (D) ‘In-line’ SE tilt image. The star marks where the near-side crater rim and the intersection of the crater floor and far-side crater wall are lined up.

Figure A3.2. Schematic cross-section of the SEM chamber with (A) the stage at 0° tilt and (B) the stage tilted to an angle (θ) where the near-side crater rim and the intersection of the crater floor and far-side crater wall are in-line. Both the near-side crater rim and the intersection of the crater floor with the far-side crater wall are marked with stars. The crater width (w) and surface to depth distance (h) are also labeled. Both diagrams are not to scale.
