General Information

Unless otherwise stated, all the chemicals used in this study were purchased from Acros or Alfa. Tetrahydrofuran (THF) was distilled from sodium benzophenone ketyl under nitrogen immediately prior to use. *N,N*-Dimethylformamide (DMF) was extra-dry grade. Other solvents were purified by standard methods.

¹H and ¹³C NMR spectra were measured on a Bruker ADVANCE2B/400MHz spectrometer in CDCl₃ or DMSO-*d*₆ using tetramethylsilane (TMS; δ = 0) as internal reference. FTIR spectra were recorded on a Bruker Vector 22 spectrometer. UV spectra were measured on a Varian VARY 100 Bio UV-visible spectrophotometer. Photoluminescence (PL) spectra were recorded on a Perkin-Elmer LS 55 spectrofluorometer. Fluorescence quantum yields (Φ_F) were estimated using quinine sulfate in 0.1 N sulfuric acid (Φ_F = 54.6 %) as standard. The absorbance of the solutions was kept around 0.05 to avoid internal filter effect. The Φ_F of spin-coated thin films of the polymers was recorded by a calibrated integrating sphere on a Photon Technology International time-resolved fluorescence spectroscopy, the detailed measuring method referred to reference [1]. Melting points (mp) were measured on Perkin-Elmer DSC-7 under nitrogen at a heating rate of 10 °C/min. Elemental analysis was performed on a ThermoFinnigan Flash EA1112. Thermal stabilities were evaluated by measuring thermo-gravimetric analysis (TGA) thermograms on a Perkin-Elmer TGA 7 under dry nitrogen at 20 °C/min. Average molecular weights (M_w and M_n) and polydispersity indices (PDI) of the hyperbranched polymers were estimated by a Waters PL-GPC-50 gel permeation chromatography (GPC) system equipped with ultraviolet (UV) detector, using a set of monodispersed polystyrenes as calibration standards and THF as the eluent at a flow rate of 1.0 mL/min. The nitrogen adsorption porosimetry was done with a Quatachrome Autosorb-1-C, and the surface area of the polymer was determined from the Brunauer-Emmet-Teller (BET) function. The thicknesses of spin-coating films of the polymers were measured by an M-2000DI spectroscopic Ellipsometer from J. A. Woollam. Cyclic voltammetry (CV) measurement of the polymer solution was performed in an electrolyte of 0.1 M tetrabutylammonium hexafluorophosphate in DCM at a scan rate of 50 mV/s at room temperature under the protection of nitrogen. A Pt wire was used as the counter electrode and an Ag/AgNO₃ electrode was used as the reference electrode.

Preparation of Polymer Aggregates

Stock solutions of *hb-P1a* and *hb-P1b* in THF with concentrations of 10^{-4} M were prepared, respectively. Aliquots of these stock solutions were transferred to 10 mL volumetric flasks, into which appropriate volumes of THF and water were added dropwise under vigorous stirring to furnish 10^{-5} M solutions with different water contents (0–90 vol %). UV and PL spectra were immediately performed once the solutions were prepared.
