## Optical Properties Calculations.

In calculation of the static  $\chi^{(2)}$  coefficients, the so-called length-gauge formalism derived by Aversa and Sipe<sup>1,2</sup> and modified by Rashkeev *et al* is adopted. The imaginary part of the static second-order optical susceptibility can be expressed as:

$$\begin{aligned} & \chi^{abc} \\ &= \frac{e^3}{\hbar^2 \Omega} \sum_{nm,l,k} \frac{r_{nm}^a (r_{ml}^b r_{ln}^c + r_{ml}^c r_{ln}^b)}{2\omega_{nm}\omega_{ml}\omega_{ln}} [\omega_n f_{ml} + \omega_m f_{ln} + \omega_l f_{nm}] \\ &+ \frac{ie^3}{4\hbar^2 \Omega} \sum_{nm,k} \frac{f_{nm}}{\omega_{mn}^2} [r_{nm}^a (r_{mn;c}^b + r_{mn;b}^c) + r_{nm}^b (r_{mn;c}^a + r_{mn;a}^c) + r_{nm}^c (r_{mn;b}^a + r_{mn;a}^b)] \end{aligned} \quad (1)$$

where  $r$  is the position operator,  $m$  and  $n$  are the valence and conduction bands, respectively,  $\hbar\omega_{nm} = \hbar\omega_n - \hbar\omega_m$  is the energy difference for the bands  $m$  and  $n$ . In order to better understand the contribution of different states to the susceptibility, the value of  $m$  and  $n$  could be tuned in our program to include some special bands.
