The content of the graphene in the G/TiN nanocomposite is about 64.6 wt%.

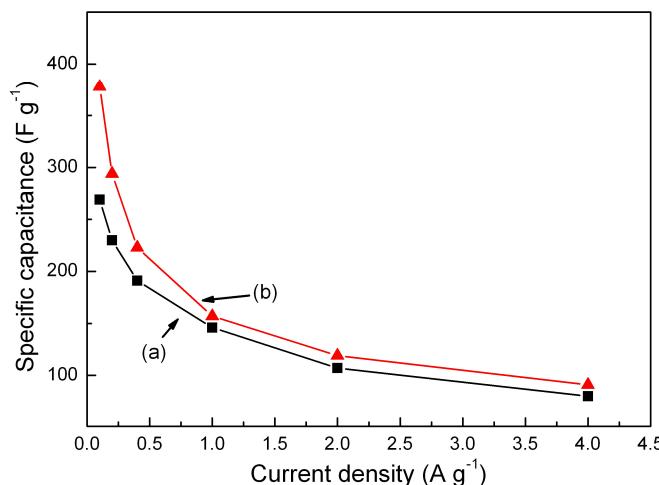

**Fig. S1** TG analysis of G/TiN nanocomposite

It is can be seen from Fig. S2, i.e., the cross-section SEM image of G/TiN nanocomposite electrode, that the graphene sheets are composed of the stack of graphene layer by layer along the c-axis. Between the layers, TiN nanoparticles play an integral role in supporting bridge. Moreover, apart from pores between 20~40 nm, there also exists pores below 20 nm.

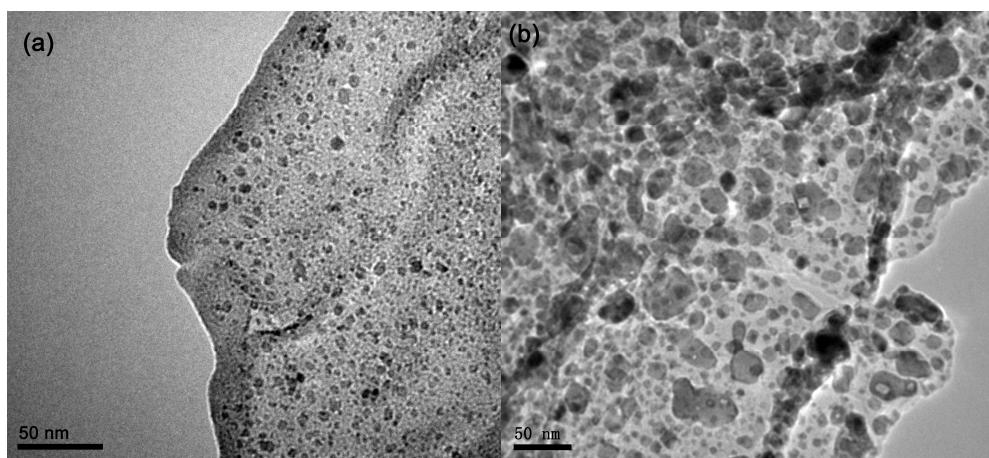

**Fig. S2** Cross-section SEM image of the electrode.

In order to clarify the ratio effect of G in G/TiN nanocomposite on the performance of the ECs, further studies were carried out. When current density is  $0.1 \text{ A g}^{-1}$ , G/TiN nanocomposite with 82.3% and 45.7% of G delivers specific capacitances of  $268 \text{ F g}^{-1}$  and  $378 \text{ F g}^{-1}$  (Fig. S3), respectively. The sample with 82.3% of G shows a relatively lower reversible capacitance, which maybe ascribe to the insufficient cover of TiN on G (Fig. S4a), thus leading to produce large amount of SEI on the surface of the electrode. As for the sample with 45.7% of G, the excess inactive TiN on G decreased the reversible capacitance (Fig. S4b) [1].

**Fig. S3** The specific capacitances as function of the current densities of G/TiN nanocomposite with different ratio of G: (a) 82.3%; (b) 45.7%.

**Fig. S4** TEM images of G/TiN nanocomposite with different ratio of G: (a) 82.3%; (b) 45.7%.
