<sup>a</sup> The vertices containing cancer genes are represented in green, and the others are represented in black. The three kinds of edges are represented by black (output), green (activation) and red (inhibition) edges, respectively.

<sup>b</sup> The frequency denotes the frequency with which a motif occurred in the original network.

<sup>c</sup> The Z-Score is the original frequency minus the random frequency divided by the standard deviation.

<sup>d</sup> The p-Value of a motif is the number of random networks in which it occurred more often than in the original network, divided by the total number of random networks. Therefore, p-Values range from 0 to 1; the smaller the p-Value, the more significant is the motif.
