Ordered arrangement of gold nanoparticles on an α -cyclodextrin-dodecanethiol inclusion compound produced by magnetron sputtering

Lorena Barrientos, Nicolás Yutronic, Francisco del Monte,

María Gutiérrez and Paul Jara*

Supporting Information Available

Commercially available Aldrich reagents were used as received. (Pelco SC-6 Sputter Coater). Working conditions: Direct current (dc) mode with a discharge of 220 V, argon pressure of 10^{-2} mbar. The gold target was sputtered at an applied power of 5.5 W. The gold deposits prepared by short- time (5 - 10 s). The size of the deposited AuNPs can be estimated with the time of exposition of the substrate.

Powder X-ray diffractograms were recorded in the range $2^\circ < 2\theta < 80^\circ$ on a Siemens D-5000 diffractometer using Cu-K α radiation (40 KV, 30 mA) and a graphite monochromator ($\lambda = 1.540598 \text{ \AA}$).

UV-Vis Reflectance diffuse Spectroscopy were measured in the range 700 to 400 nm on a Shimadzu UV-2450 with ISR-2200 Integrating Sphere Attachment, this instrument is controlled by the software UVProve Version 1.10.

The TEM image and diffraction pattern was recorded in a 200keV JEOL2000FX.

The AuNPs were characterized by using a Leo 1420VP scanning electron microscopy.

The Raman spectra at 514 nm were obtained using a Renishaw Raman microscope (System RN 1000) equipped with a Leica DMLM microscope and an electrically refrigerated CCD camera. The output laser power was in range 1.0-3.0 mW.
