Supporting Information for

Improved lithium cyclability and storage in a multisized pore ("differential spacers") mesoporous SnO$_2$

Konda Shiva$^a$, S. Asokan,$^b$ and Aninda J. Bhattacharyya$^{a,*}$

Supporting information 1: N$_2$ adsorption-desorption isotherms for SnO$_2$-M at 350 °C and 400 °C respectively

Supporting information 2: TEM images of various samples at low resolution showing absence of any special particle morphology. Only randomly arranged particles are observed.
Supporting information 3: Thermogravimetric analysis (TGA) of before sintering sample and sintered samples. The sample sintered at 500 °C shows the least weight loss among all the samples. However, based on BET and galvanostatic cycling 500 °C was not selected as the appropriate sintering temperature for the work presented in the manuscript. The sample sintered at 350 °C was found to be most suitable and all characterization with respect to this are presented in the manuscript. The sample sintered at 500 °C showed very poor cyclability due to lower surface area due to loss of mesoporosity. The particles probably possess a solid-like morphology.
